Advances in Criminology, Criminal Justice, and Penology (ACCJP) Book Series

Liam J. Leonard
Northern Arizona University, USA

ISSN:pending
EISSN:pending

MISSION

Criminology has never been more relevant. Violence, serial murder, crime and victimization continue to remain an unfortunate staple of society. Crime is a key issue globally, nationally, and regionally. Law enforcement personnel within the criminal justice system must keep pace with ever changing modes of crime. As officials work to predict and prevent crimes, as well as apprehend offenders, they will need to devise new tools and strategies to preserve the safety of society and ensure proper justice is served.

The **Advances in Criminology, Criminal Justice, and Penology (ACCJP)** Book Series explores emerging research behind crime control strategies, crime motivation, new methods and the utilization of technology for committing illegal acts, criminal justice and reform strategies, and the effects of crime on society and its victims. The publications contained within this series are valuable resources for government officials, law enforcement officers, corrections officers, prison management, criminologists, sociologists, psychologists, forensic scientists, security specialists, academicians, researchers, and students seeking current research on international crime.

COVERAGE

- Policing
- Restorative Justice
- Fraud
- Criminal Psychology
- Penal System
- Criminal Justice Systems
- Serial Murder
- Human Trafficking
- Criminology
- Law

This book is dedicated to the memory of my late father for the love and care that he always displayed for his family, and for teaching me the importance of humanitarianism. Also, to my wife, Olga, and our son, Darius, for filling my life with so much love, joy, and happiness.

Preface

Technological advancements of the past few decades, particularly those related to the world wide web, have provided new platforms and outlets for criminals to conduct unlawful and unethical behavior. Sadly, these criminals have identified ways to both use and exploit this technology for devious means, ranging from data breaches, theft, cyberstalking, embezzlement, human trafficking, child abuse, to many other cunning actions that are impacting individuals, corporations, and government entities all over the world. These days, innocent law-abiding citizens are under constant attack by these cybercriminals and it's drastically affecting every aspect of their daily life, whether they are aware of it or not.

Over time, individuals, governments, law enforcement agencies, and businesses have been advancing their data harvesting, tracking, and management techniques to collect information about web users and their online activities with the hope of better understanding their digital footprints. While they mean no harm and are merely trying to more efficiently target their efforts and increase their overall data integrity, the reality is that there are millions of cybercriminals out there who have much more devious intentions in mind and are using these practices to gather private data information about individuals and organizational entities for exploitative purposes.

Even with the web being prevalent for decades now, most still do not understand that there is no real privacy online, and as such so much information about individuals and groups is continually being shared out either publicly or within personal accounts and online groups. Criminals are just waiting for the opportune moment to seize information from these so-called trusted environments as they now have access to hidden portions of the world wide web, better known as the “deep web”, where they can freely access and share private information about everyone and everything.

While the deep web consists of sites that simply cannot be found through traditional search engines, the “dark web” emerged as a portion of the world wide web that was intentionally hidden, operating under extreme secrecy and inaccessible through standard browsers. Criminals can navigate through these sites anonymously, leaving no trackable digital information behind. The deep web has become an ideal source of information for criminals engaging in a range of illegal activities such as human trafficking, child exploitation, murder, and selling social security numbers, drugs, and many more illegal goods and services.

Although most individuals around the world are not very familiar with the existence of the deep web and do not know how the deep web can affect them and their personal privacy, these sites present significant threats to all people and organizations worldwide. Regrettably, the primary source of information that is available on the deep web and utilized by these criminals happens to be provided freely and willingly by all those uninformed individuals and organizations that post personal and proprietary

information across social media and other online channels. They do not realize that by sharing information such as their birth date, their home address, and pictures of themselves and of their loved ones, that they are putting themselves and others at risk.

This seemingly private information can be easily accessed by cybercriminals which is then shared through the deep web all over the world. Cybercriminals worldwide can be very technology savvy and highly intelligent individuals who can hack bank accounts, social media accounts, websites, private networks, etc. and in many cases can easily persuade average users to reveal confidential information through fraudulent e-mail messages known as phishing attacks. They can stalk and harass their victims online and through gaming platforms, sometimes even using these mediums to lure them to a physical meeting place where they can kidnap, assault, or kill their victims. Regrettably, many minors and children are the primary victims of these luring criminal schemes.

On an even larger scale, the deep web also threatens many organizations, businesses, governments and their thousands, millions, or even billions of employees, customers, and citizens globally. These entities can be subject to cyberattacks, that can lead to credit theft, embezzlement, service disruption, the stealing of trade secrets, the sharing of confidential information, and in some cases the use of a denial-of-service (DoS) attack for ransoms. These activities also have significant implications on governments as they provide the anonymity ideal for spying on each other and provides individuals with the opportunity to sell government secrets with less risk, and in some cases even having the ability to rig democratic processes and elections. Ironically, the deep web also provides the concealment necessary for hacktivists to illegally reveal the personal information of the individuals that are committing such illicit activities.

As the deep web become more widely known as a primary source of illegal goods and services offered by criminals, there are calls for government regulations and policies to be put in place, leading to controversial discussions as to whether one country's government can place restrictions on an international tool and whether de-anonymizing the dark web is an infringement on individual rights. Currently, in most western societies, internet access and data privacy remain a heated issue with government officials attempting to navigate new policies that will better secure their citizens' online information. Many governments and their laws have not kept pace with the rapid increase in the use of the deep web for criminal activities, which is providing cybercriminals fertile ground for committing such actions. Although government policies and laws are extremely essential in dealing with these problems, the best way to truly deal with these threats that the deep web poses is through knowledge transmission, as the public needs to become much more knowledgeable and aware of these realities and ways that they can protect themselves.

Academics and researchers play a significant role in assisting the general public with learning more about these phenomena and ways to deal with them. As cybercriminals develop more advanced strategies to expand their criminal enterprise, society needs to become much more knowledgeable and educated about ways to combat these threats and cyberattacks that are costing many people and organizations around the world tremendous pain, anguish, discomfort, and billions of dollars in damages. Users of the world wide web can become collectively much more aware of protecting themselves and denying criminals access to private and personal information.

To facilitate the knowledge development process and provide the latest research discoveries on this relevant topic, the *Encyclopedia of Criminal Activities and the Deep Web* is a three-volume compilation that showcases recent findings, trends, challenges, and solutions brought forth by hundreds of promi-

ment researchers and experts from all over the world. With 79 individual article contributions containing very thorough coverage of all aspects of criminal activities related to the world wide web and the various challenges they pose to all societies and their citizens and organizations, this comprehensive encyclopedia substantially contributes to the body of literature surrounding the controversial use of the dark and deep web.

This publication serves as an excellent source for the latest discoveries in this area and will benefit criminologists, forensic scientists, sociologists, journalists, victim advocates, academicians, researchers, and students who are looking to gain further knowledge about cybercriminals and the deep web, and will empower law enforcement agencies, government officials, and policy and law makers to enact solutions for the protection of society. Furthermore, information technology specialists, cybersecurity analysts, data scientists, and other industry professionals will also greatly benefit from this extensive research which will ideally inspire new methods of data security and protection.

The *Encyclopedia of Criminal Activities and the Deep Web* is designed to act as a sole reference source on conceptual, methodological, and technical aspects, and will provide an understanding of emerging topics including, but not limited to: cyber harassment, internet privacy, cyber espionage, darknet, social engineering, online gaming, online phishing, social networking, hacktivism, and cyber law. The article manuscripts included in this publication have all been subjected to a double-blind peer review process and have satisfied all review requirements and were accepted by the reviewers of this publication. The contents of this publication are certain to provide readers the necessary means for further research and innovation in their relevant area of research related to the theme of this publication.

The *Encyclopedia of Criminal Activities and the Deep Web* is organized into five separate sections that provide comprehensive coverage of critical topics. The sections are:

1. Cybercriminal Profiles, Understanding Cybercrime, and the Realities of the Dark Web;
2. Cyberwarfare, Cybersecurity, Spyware, and Regulatory Policies and Solutions;
3. Drug Trafficking, Human Trafficking, and the Sexual Exploitation of Children;
4. Financial Fraud, Identity Theft, and Social Manipulation Through Social Media; and
5. Security Tools and Solutions, Human-Based Cyber Defense, and the Social Understanding of Threats.

Each of the focused sections include diverse articles centered around a common theme, with each of the articles then arranged by relevance to the theme and to each other. Two different tables of contents support the reader with navigating the contents by volume and alphabetically. Below are just a few highlighted article contributions.

SECTION 1: CYBERCRIMINAL PROFILES, UNDERSTANDING CYBERCRIME, AND THE REALITIES OF THE DARK WEB

This section provides a broad publication overview of what constitutes cybercrimes and studies into the motives behind cybercriminals. Additionally, it provides the reader with a greater understanding of the deep web and contemporary challenges posed by these sites. The first article in this section is titled “Cybercrime” and is authored by Profs. Poongodi Thangamuthu, Anu Rathee, Suresh Palanimuthu, and

Balamurugan Balusamy from Galgotias University, India. It explores the various forms of cybercrime and how they can threaten an individual or even an entire nation's security. Another article presented early within this section, "Crime-Fake News Nexus," authored by Profs. Xingyu Chen, John Yu, Pamela Goh, Loo Seng Neo, Verity Er, and Majeed Khader from Home Team Behavioural Sciences Centre, Ministry of Home Affairs, Singapore, examines 32 cases of fake news incidents that were perpetrated for criminal gain, which took place in Singapore from 2013 to 2018 and aims to look at the impact that these stories have had throughout Singapore. Also included in this section is the article, "Privacy, Ethics, and the Dark Web," authored by Prof. Richard T. Herschel from Saint Joseph's University, USA, which considers how companies are actively monitoring activities on the deep web as new legislation requires them to inform authorities if there has been a data breach that affects their customers. One of the closing articles, "Academic Integrity of Global Digital Masked Bandits Lurking the Deep and Dark Web," authored by Profs. David B. Ross, Julie A. Exposito, Rande W. Matteson, and Melissa T. Sasso from Nova Southeastern University, USA and Courtney E. Matteson from Orange County School District, USA, looks to enlighten teachers and administrators about the growing concern of plagiarism and deep web schemes to defraud funding sources and how they can become proactive in handling it within their own classrooms and schools. The final article within this section, "Development of Crime Sociology from Bureaucratic Iron Cage to Digital Determination," authored by Prof. Muhammet Ali Köroğlu from Uşak University, Turkey, explains how humans have always had values, norms, and rules and how these have been affected by the advent of digital technologies.

SECTION 2: CYBERWARFARE, CYBERSECURITY, SPYWARE, AND REGULATORY POLICIES AND SOLUTIONS

This section consists of content dealing with an in-depth review of cybersecurity challenges to global governments, including research on cyber espionage, whistleblowing, and hacktivism, as well as international regulations and solutions to combat and prevent online illicit activities. The first article included in this section, "The Globalization of Hybrid Warfare and the Need for Plausible Deniability," authored by Prof. Benedict E. DeDominicis from Catholic University of Korea, Korea, looks at how social media can be used as a weapon to distribute propaganda and disinformation effectively and extensively at a low or free cost and aims to strengthen surveillance capabilities to prevent its influence in significant events such as presidential elections. Another noteworthy article included in this section is "The Spy Who Never Has to Go Out Into the Cold," authored by Prof. Laura Pinto Hansen from Western New England University, USA. This article discusses how spies utilize the dark and deep web to make covert operations even more secretive and explores methods of obtaining sensitive information and disabling computer systems. Also included in this section is the article "Hacktivism and Alternative Journalism: The Case of the French YouTube Channel Thinkerview," authored by Prof. Christophe Emmanuel Premat from Stockholm University, Sweden, which explores a hacktivist YouTube channel from France and studies how the channel presents the guests and the topics to see if there is journalistic innovation. One of the closing articles in this section, "Regulating the Internet," authored by Prof. David T. A. Wesley from Northeastern University, USA, reviews the legal history of computer code as free speech in the United States and how it can be used to promote other forms of free speech through cryptography and other secure communications. It also argues that the deep and dark web are direct results of these precedents

and while they can be abused by cybercriminals and malicious state actors, they are also indispensable in promoting free speech and human rights. The last article within this section, “Game Consoles Protection and Breaking It,” authored by Prof. Nezer Jacob Zaidenberg from the College of Management, Israel, surveys attacks on various game consoles and explores the motivations behind these attacks, the way the console manufacturer acted, and the way the hacking community reacted.

SECTION 3: DRUG TRAFFICKING, HUMAN TRAFFICKING, AND THE SEXUAL EXPLOITATION OF CHILDREN

This section examines the influence of the deep web in aiding drug and human trafficking activities, as well as how it provides a protected outlet for the exploitation of children. Additionally, all forms of cyber aggression, including cyber stalking and cyberbullying are analyzed. The first article in this section, “Drug Trafficking,” authored by Prof. Prabhjyot Kaur from University of Delhi, India, and Prof. Puneet Kumar Kaushal from Lucideus Technologies, India, reviews how the deep web and dark web operate as it pertains to the sale and trade of illegal drugs online and also looks at new tactics that law enforcement are using to prevent this from happening. Another article included in this section, “Web-Based Child Sexual Exploitation,” authored by Prof. Lacey Nicole Wallace from Penn State Altoona, USA, explains online child sexual exploitation, describes the law in regards to these activities, details what is known about victims and offenders, and highlights current efforts toward prevention and intervention. Additionally included within this section is the article titled “Cyberstalking” authored by Prof. Edith Huber from Danube University Krems, Austria and Prof. Roman H. Brandtweiner from Vienna University of Economics and Business, Austria, which examines the digitalization of stalking and how it has created new crimes such as cyber harassment, cyberbullying, and other romance scams. One of the closing articles in this section, “Tech That, Bully! Defeating Cyberbullying With Its Own Weapons,” authored by Profs. Maria Rosa Miccoli, Giulia Gargaglione, and Valentina Rotelli from Catholic University of Milan, Italy; Profs. Simone Barbato and Lorenzo Di Natale from Idego - Digital Psychology Srl, Italy; and Prof. Valentina Silvestri from University of Milan - Bicocca, Italy, looks at new treatment options for cyberbullying victims including the use of a virtual reality tool which will help victims overcome their distress in a safe and protected environment. The last article within this section, “Cyber Crime Against Women and Girls on Social Sites in Bangladesh,” authored by Prof. Fardaus Ara from Rajshahi of the University of Bangladesh, Bangladesh, presents new information on cybercrimes that have been committed against women and suggests new ways to control and combat cybercrime for the future.

SECTION 4: FINANCIAL FRAUD, IDENTITY THEFT, AND SOCIAL MANIPULATION THROUGH SOCIAL MEDIA

The articles included in this section investigate challenges to internet and data privacy and the social engineering attacks that can lead to identity theft. The emergence of bitcoin and e-banking fraud are also discussed. The first article within this section, “Internet Privacy,” authored by Prof. Nathan John Rodriguez from Weber State University, USA, examines the risks of submitting personal information

online and why users may choose to exchange their personal information for a more personalized online experience. Another article included in this section, “Social Engineering Using Social Networking Sites,” authored by Prof. Roberto Marmo from University of Pavia, Italy, explains what social engineering is and it offers techniques and solutions for social engineering attacks that occur on social media websites. Another article presented in this section titled “Online Phishing and Solutions,” authored by Profs. Ping Wang and Anteneh T. Girma from Robert Morris University, USA, discusses how online phishing works to exploit human vulnerabilities and offers a comprehensive set of possible solutions to address the problem. One of the closing articles in this section, “Cybercrime in Online Gaming,” authored by Prof. Boaventura DaCosta from Solers Research Group, USA and Prof. Soonhwa Seok from Korea University, South Korea, explores cybercrimes such as data breaches, compromised and stolen data, and the theft and sale of in-game items, as it relates to the video game industry. The last article within this section, “Preliminary Insights Into the Adoption of Bitcoin in a Developing Economy,” authored by Profs. Frederick Edem Broni, Richard Boateng, and Acheampong Owusu from University of Ghana Business School, Ghana, looks at bitcoin adaptation specifically in Ghana and assesses whether or not bitcoin is preferable to other methods of payment online.

SECTION 5: SECURITY TOOLS AND SOLUTIONS, HUMAN-BASED CYBER DEFENSE, AND THE SOCIAL UNDERSTANDING OF THREATS

This section provides innovative solutions for combatting cyber threats including new technologies and tools, as well as human-based methods that can be enacted to increase awareness. The first article within this section, “The Importance of the Human-Centric Approach in Combating Cyber Threats,” authored by Profs. Pamela Goh, Loo Seng Neo, and Xingyu Chen from Home Team Behavioural Sciences Centre, Ministry of Home Affairs, Singapore, looks at the prevalence of cyber threats and cyberattacks and provides solutions and recommendations as to what people can do to protect themselves personally and professionally. Another article presented in this section is “Online Expression, Personal Cybersecurity Costs, and the Specter of Cybercrime,” authored by Profs. Juhani Rauhala and Pasi Tyrväinen from University of Jyväskylä, Finland and Prof. Nezer Zaidenberg from College of Management Academic Studies, Israel, examines the security and privacy risks that come with everyday internet use and also looks at what can be done to mitigate those risks in the future. Another noteworthy article titled “An Overview (and Criticism) of Methods to Detect Fake Content Online,” authored by Prof. Antonio Badia from University of Louisville, USA, discusses the issue of fake content online and proposes both human and algorithmic methods to solve the issue. One of the closing articles, “Hybrid Artificial Intelligent Multi-Layer Blockchain and Bitcoin Cryptology (AI-MLBBC),” authored by Prof. Murad Al Shibli from Abu Dhabi Polytechnic, UAE, provides new information on blockchain and bitcoin cryptology and explains new solutions that can be used to prevent hacking. The final article within this section, “ARM Hypervisor and Trustzone Alternatives,” authored by Prof. Nezer Jacob Zaidenberg from College of Management, Israel and Profs. Raz Ben Yehuda and Roee Leon from University of Jyväskylä, Finland, discusses the hypervisor vs. TrustZone™ implementation dilemma and explores new solutions.

Criminal activity and the world wide web are no longer a peripheral research topic. Instead, this is a very fast-growing research area which requires a tremendous amount of participation and collaboration by researchers from all over the world. The *Encyclopedia of Criminal Activities and the Deep Web* will aid in efforts to better understand and deal with the ever-growing societal problems and challenges that such devious activities present to individuals and organizations all over the world.

The diverse and comprehensive coverage offered within these articles will contribute to a better understanding of all topics, research, discoveries, and solutions in this evolving field. This publication will inspire its readers to further contribute to the current body of knowledge in this immense field, creating possibilities for further research and discovery into the future understanding of the dark side of the world wide web and how this technology has been overlooked in the past as an element of crime all over the world.

Mehdi Khosrow-Pour, D.B.A.

Editor-in-Chief

Encyclopedia of Criminal Activities and the Deep Web

Acknowledgment

Editing and completing an authoritative and comprehensive scholarly research publication such as the *Encyclopedia of Criminal Activities and the Deep Web* requires tremendous contributions, and a great deal of assistance from large groups of scholars and staff. The primary objective of this encyclopedia is to provide the most up-to-date scholarly coverage of all topics related to the evolving nature of criminal activity, especially online.

The contributed chapters from experts all over the world provide an in-depth look into topics such as cyber stalking, cyberterrorism, dating websites and crime, drug trafficking, e-banking fraud, gaming and crime, human trafficking, identity theft, online blackmail, online hate crimes, online predators, social media deception, vigilante justice, internet privacy information, cybersecurity legislation, child exploitation, internet regulations, international regulations on the dark web, and much more. I am indebted to all the authors for their excellent contributions to this publication.

All submitted manuscripts to this publication underwent a double-blind peer review process in order to achieve the highest level of quality and accuracy. I am thankful to all the reviewers of this encyclopedia for providing their expertise and their rigorous, unbiased assessment of the manuscripts assigned to them on a double-blind basis, as well as the members of the Editorial Advisory Board for their wisdom, guidance, and assistance with various decisions throughout the editorial process.

I would also like to convey my deep appreciation and gratitude to all those individuals who assisted me in editing this publication, which include Lindsay Wertman, Managing Director of IGI Global, Melissa Wagner, Managing Editor of Acquisitions at IGI Global, Chris Shearer, Copy Editing Manager at IGI Global, and Michael Brehm, Managing Editor of Book and Journal Production at IGI Global. Additionally, I would like to thank the IGI Global Sales and Marketing Department, especially Nick Newcomer, Senior Director of Marketing and Sales and Caroline Campbell, Marketing Manager, for their endless support in promoting this invaluable reference source.

Thanks to everyone who has provided me immeasurable amounts of knowledge, wisdom, and support over the last 30 years.

Mehdi Khosrow-Pour, D.B.A.

INTRODUCTION

The cybercrime prediction over the past year says about the damage cost by tracking the activities in government officials, industry experts, cybersecurity companies, universities, colleges, media outlets globally. A criminal way of doing an activity through the use of digital devices and internet by a group of people is known as cyber crime. The critical issue of cyber crime is pulling everyone's attention across the world. Due to the fast growth in e-commerce, e-governance, social networking and various other e-services cybersecurity has a growing challenge where database is easily collected and misused. Cyber attacks are more pervasive and threats to critical infrastructure and lack of security and underreporting makes industrial systems and products more vulnerable. Internationally, the most affecting problems are mass-ransomware attacks and valuable data theft much more in the last few years. Lack of electronic evidence in cybercrime and proper convergence between private, and government institutions are making difficult to seize and stop criminal financial transactions. Based on historical cybercrime statistics, there would be a dramatic increase in crime gang hacking activities and the cyber attack surface will be an order of magnitude greater in 2021 than today. According to the prediction of cybersecurity ventures, the cybercrime will cost the world \$6 trillion annually by 2021, up from \$3 trillion in 2015. The estimated cyber security cost is rapidly growing to \$170 billion dollars in 2020 that was only \$75 billion Dollars in 2015. The European countries, making the directives used to protect the information in systems from threats, the first directive is EGDPR (European General Data Protection Regulations) and the second directive is NIS (Network Information Security).

The criminal activity of cybercrime includes the theft of intellectual property, damage and destruction of data, theft of personal data, stolen money, forensic investigation and reputational harm. Cybercrime is an online threat that can be committed by targeting the computer devices, computer networks and the automated processes performed through the use IT systems by creating and distributing malwares or viruses. Cybercrime allows attackers to penetrate in a well-controlled environment and the malicious activities remains untraceable. As it is a rapid growing area of crime, criminals exploit the convenience, speed, anonymity of the internet and committing various criminal activities by posing different threats

DOI: 10.4018/978-1-5225-9715-5.ch001

Figure 1. Cybercrime process

to victims worldwide on an unprecedented scale. The cyber crime process is explained in the following: Initially, the developer writes the malware code. Hacker uses the malware to exploit the credentials of victim's personal computer. For instance, bank account credentials are revealed to hackers from the victim's computer system and the hacker acquires the credentials of the target by compromising the server. The attacker gains the remote access to an individual's financial account in the victim's system and it is being stolen by manipulating the account from the concerned targeted bank by compromising the proxy server. The stolen fund is transferred to the money mule bank account and then it is transferred to criminal organization. The process of cybercrime is depicted in Figure 1.

Cyber attackers have the objectives for which they do cybercrime / cyber-attack (Kumar et al, 2014; Rawat et la, 2015). Significant objectives of cyber attackers are discussed below:

Entertainment

Some cyber attackers are performing criminal activities to examine their hacking abilities. Such persons are interested in getting fame in the cybercrime world. They feel proud of their successful attempts that were not achieved by any other attacker or some attackers failed to execute such kind of attack.

Hacktivists

These kinds of cybercriminals are stimulated by religious, social and political ends. Their intention is to inculcate the religious and political mottos among people and to depress them. It is an attempt of extending the religious or political popularity among the crowd. Recently, hacktivists are revealing the individuals secret affairs via social web sites.

Financial Gain

Attackers in this category desire to grow rich by performing criminal activities and focusing the financial gain. The targeted domain may be the large organization, banking systems, rich persons, or wealthy countries. Such type of attackers may be hired by some companies, individuals or countries for performing attacks.

Spying

In this category, the cybercriminals try to steal the confidential information of any specific individual, organization, or country. The spy hackers will work for their client's need and avail the payment in return.

Revenge

These kinds of cybercriminals may be formed because of irritated, humiliated and expelled employees. These persons knew the secret, weak points and policies of their organization, or country. The hackers perform their cyber-attacks by focusing the emotion of hate to take the revenge in the form of spoiling the reputation, financial loss, tarnishing the social image and so on.

Everyone in cybercrime is performing some task to fulfill their objective i.e., to gain the advantages in the perspective of money, revenge or any other motive. Various roles of criminal organizational members in cybercrime are shown in Figure 2.

Different Perspectives of Cyber Crime

Cyber crime is broadly viewed as three categories based on the techniques and difficulty level (Haughn et al, 2017; Arlitsch et al, 2014).

Crimes Against People

In this category, a person disseminates illegal or fake information online which includes cyber stalking, harassment, child pornography, human trafficking, credit card fraud, identity theft and spoofing.

Figure 2. Criminal organization members in cyber crime

Crimes Against Property

Cyber criminal illegally gain access to get the confidential information such as individuals credit card details, make online purchase, and to execute phishing scams. It generally includes hacking, DDoS attacks, computer vandalism, copy infringement, cyber and type squatting.

Crimes Against Government

This type of crime is committed against government by hacking military websites, government websites, or distributing propaganda. It is an attack on nation's sovereignty and performed by terrorists or enemies of other nation. The cybercrime activities against the government comprise accessing confidential information, cyber terrorism, cyber warfare, and pirated software.

Taxonomy of Cybercrime

Cybercrimes are described as global crimes because they go beyond the geographical boundaries and can be perpetuated from anywhere against any individual or technology. The most occurring crimes in today's world are cybercrimes. Hackers are searching for new attack patterns that increase the complexity for security professionals to defend the data and resources on the internet (Singh et al, 2016). Hackers are affording free attack tools to increase the number of attack rate in the internet. The massive increase in e-services like online banking, online shopping and social apps gives a huge rise in the number of internet users which paves a way for easy target by cybercriminals (Wall, 2002). Some of the cyber crime activities happening in today's world are described below:

CYBER PEDDLER

Stealing confidential data from the computer system connected to the internet. There are two types of cybercrime in this activity,

Cyber Fraud

It is a fraudulent activity of making personal or financial gain by deception. It encompasses social engineering attacks like spear phishing, password guessing and DNS redirecting in which the attacker will acquire and use the confidential information of various users.

Cyber Activism

Social applications are used to create, operate, manage the activism and the information will be distributed to large number of users in few seconds. The communication technologies used are WhatsApp, Twitter, YouTube, Facebook, Gmail, LinkedIn, etc. Moreover, these technologies have been made for affording better connectivity with colleagues, friends and the latest information can be reached quickly to a wide geographical area. But the person with wrong intention uses these technologies for spreading rumour to spoil the image or sending false information about individuals or organization to avail some benefits.

CYBER VIOLENCE

1

It means the violence is created using any device (like smartphone) or computer system connected to the internet. The impact of “violence” will be harmful and the components that are affected may be the data on servers, devices connected to the internet, and any individual or entire organization can be devastated by cyberviolence. The different forms of cyberviolence are discussed,

Cyber World War

The violence created at maximum level that affects many countries in the world. The cyberworld war may act upon an individual, whole country, military sector, private as well as government employees. The main goal of this attempt is malfunctioning or to disable, destroy the infrastructure of any adversary and to attain the victory of the targeted country.

Cyber Terrorism

Some set of people has only the aim of destroying the peace of humanity known as terrorists. They believe that the thing they are doing is right to enrich their religion stronger in the world or they have the privilege to command over the world or no other can be powerful than them. These kind of malicious activities in the digital world are referred to as cyberterrorism. The people who are involved in these activities will not have any sympathy or emotions. They will behave like machines for using any type of attack to fulfill their objective.

Cyber Stalking

It is a crime in which the attacker annoys a victim through the electronic communication by sending e-mail or instant messages (Sreenivasulu et al, 2013). A cyberstalker utilizes the anonymity in the internet to stalk the target without being detected. The most precautionary way is to use primary e-mail account only communicating with the trusted persons and maintain anonymous mail account for all other communications. Moreover, it is suggested that not to place any personal details in an online profile.

Cyber Revenge

It is a criminal activity which is harmful against someone in reaction to one's previous action. The main objective is to destroy the adversary by revealing the confidential information, forming the false image in the internet system, and destroying computer based resources. Revenge hacking encompasses the extensive set of drive behind cybercrime. The victimized industries have to face various forms of cyber-attack that links back the own hostile policies or actions towards the attackers. A target server is considered as the source of a threat and in particular, it may be the component of a hospital, public utility or any municipal authority. Attackers comprise a server as a proxy one for launching attacks across the global. Moreover, there is a constant probing in automated systems that can easily allow cracked access credentials.

CYBER SQUATTING

In this type of cybercrime, the attacker registers the name of the trademark of others illegally as their domain name such that the owner fails to register the domain name with their own trademark. The different types of cybersquatting are as follows:

Classic Cyber Squatting

The main goal of the cybersquatter is to obtain ransom from the target. Once the cybersquatter gets paid from them, then the attacker deletes or sells off the domain name. Nowadays, due to enforcement of laws this type of attack is not more popular.

Derogatory Cyber Squatting

In this category, the attacker tries to destroy the reputation of the target. The illegitimate activities are done by uploading violated contents, hate speech or any pornographic material on the domain name.

Typographical Cyber Squatting

In this type of attack, the hacker cannot use the same name of the trademark because the domain name is already being registered by the owner of the trademark. Hence, the hacker uses the domain name very similar to the original one. For instance, if the hacker is using the registered domain name such as Yahoo mail which is very similar to Yahoo mail, then the adversary may succeed to make some losses for the original trademark owner.

CYBER TRESPASS

Trespass refers to the illegitimate activities that someone crosses boundaries for accessing the information without any authorization. It is the crime where cyber law is violated by accessing an authorized user system. It also violates the fundamental security services such as integrity and confidentiality. The various types of cyber trespass are discussed below:

Cyber Theft

Theft is a threatening activity that something is stolen or damaged. In real world, damaging or stealing something physically into someone's property like in organization or houses and stealing some valuable things such as file, gold, and so on. Cyber theft in cyber world is occurred by technically hacking computer system connected to the internet. The main objective of hackers in cybercrime is to steal data in the cyberspace for personal or financial gain. Basically, the theft in cyber crime can be done in two ways:

Theft to Data/Information

Some confidential information of organization, individual and country can be hacked. Various security services like confidentiality, integrity and availability of information must be managed carefully from cyber attackers.

Theft to Cyberspace

Cyberspace is not able to manage in a controlled manner then it leads to malfunction. Hackers have the objective of stopping the target services or attack them directly in the cyberspace.

Cyber Espionage

It refers to cyber spying and it is an act of monitoring the activity of individual, organization, company, country, rival or enemy by carrying out the malicious activities in the network. These activities are performed by technically strong persons which are difficult to trace. Attackers start analyzing the network traffic illegally, uses laptop cameras and security cameras to acquire the information about targets, i.e., some personal information like what kind of work they are doing, type of information they are accessing etc.

a) Cyber pornography

Cyber pornography is the act of using cyberspace to create, display, distribute, import, or publish pornography or obscene materials, especially materials depicting children engaged in sexual acts with adults. Cyber pornography is a criminal offense, classified as causing harm to persons. In this type of attack, the attacker uploads sexual material of a person on public websites. One of the biggest publicized catches of child pornography perpetrators was launched in May 2002 and called Operation Ore. The intruder will hack the private pictures of a person by targeting their mobile, tablet, security cameras or computer system. Exposing private pictures or videos makes embarrassed to the target of an adversary. In some extreme cases, the person commits suicide attempt also.

GENERAL DESCRIPTION OF CYBER ATTACK

The monitoring, regulation, protection, and enforcement related to cybercrimes are not solely responsibilities of state-controlled public police. This stresses the need for alternative strategies to cope with the policing deficit. A possible strategy to overcome such problems is an integral approach, which is an approach wherein all relevant stakeholders—public as well as private—participate in the implementation of safety and security policy. An outgrowth of such an integral approach is a Public–Private Partnership (PPP). To provide this safety to the people cyber attacks are basically categorized into violent and non-violent as depicted in Figure 3. The violent category of cyber attacks includes cyber terrorism, stalking, bullying, pornography. Non-violent cyber crime comprises of fraud, cyber theft hacking. Cyber Bullying is most common over past five years; In this, generally the people below eighteen ages are more susceptible as per the study. Cyber Bullying is a threat when a person receives negative comments or pictures from the person on another side.

Figure 3. General category of cyber attack

A variety of cyber-attacks are tremendously increasing day by day in the world of internet and it continues to evolve. Attackers gain access to the system, locking sensitive files, leaking proprietary information to the public, and stealing mission-critical information. Moreover, it is very hard to recover from such types of attacks in large scale enterprises (Zulkefli et al, 2015). Many cyber-attacks are immensely destructive which follow diverse strategies to capture different ends. Ransomware is the malicious software designed to damage or controls the computer system. Phishing introduces fake official emails, fake websites where victims log in and enter their passwords. In Man-in-the-Middle attack, hackers insert themselves between the computer and the web server. Distributed Denial of Service overloads the server with bogus data leads to unavailability of service. Cross-Site Scripting injects the malicious code into a website which target's the victim's browser. SQL injection attack corrupts data to make a server disclose the sensitive information such as credit card number, username etc. The block diagram of cyber-attack is given in Figure 4.

Some of the most significant cyber-attacks are explained in the following sections.

Ransomware

Ransom malware or ransomware is the digital version of kidnapping, which prevents the normal users for accessing the personal files from their system and demands for random payment to regain the access. The first version of ransomware was originated in late 1980s and the payment was to be paid through snail mail. Nowadays, the ordered payment is to be sent via credit card or cryptocurrency. Typically, hacker

Figure 4. Block diagram of cyber attack

places the ransomware file in the targeted server and follows some form of phishing for transmitting the malicious file along with email of an intended user. Once the user opens the file, the malicious ransomware file is deployed in the user's system and encrypt, locks the highly sensitive files. If the user tries to open the file, they are intimidated with the message as "files have been locked". It is possible to receive the encryption key once the user paid the specified amount to the hacker, usually done through bitcoin payment which is untraceable. However, over 85% of the malware targeting medical devices in 2018 was ransomware. Ransomware attacks of 2017, namely, Cerber and Jaff. Cerber is a family of ransomware payloads which are distributed through exploiting kits, email, JavaScript, and Microsoft Word macros. Variants of Cerber include a Bit-coin wallet stealing function. Jaff is described as new but vicious. It is spread via the Necurs botnet and is downloaded in a .pdf file attachment. Jaff is said to check for the target computer's language setting. This attack is massively growing in the recent years and some of the ransomware are mobile ransomware, leakware, doxware, encrypting or non-encrypting ransomware.

Internet of Things

Internet of Things is made up of digitally connected devices to the internet which makes people lives easier (Sadeghit et al, 2015; Weber et al, 2016). IoT sector is anticipated to grow up to 20.4 billion devices by 2020, and the business sector is expected to spend \$134 billion by 2022 only for cyber security on IoT devices. The IoT devices are more vulnerable to various types of attacks. The associated gadgets or machines are a great degree profitable to digital attacker for few reasons. Most IoT gadgets work unattended by people is very simple for an attacker to physically access them. Most IoT parts impart over remote systems where an attacker could acquire private data by listening in. Many IoT devices are puzzled with security holes, where hackers can pass through easily to accomplish malicious activities. It leads to catastrophe on a large scale and in 2016, IoT attack was launched that ends in huge portions of the internet become inaccessible. In workplace, the average number of IoT devices is anticipated to increase from 9,000 to 24,762 devices. This issue presents a significant threat to all organizations, because more IoT devices are interconnected to the network.

Social Engineering and Phishing

In social engineering attack, attacker prefers the human interaction to compromise the computer systems or an organization (Yar et al, 2013). An attacker pretends to be a researcher, newly joined employee, offering credentials to support the identity. Spear-Phishing refers to identify and prevent the targeted email attacks which are entering the organization (Sood et al, 2013). Attackers in phishing attack broadcast a large net in the anticipation of catching anyone, whereas spear-phishing attackers highly focusing the targeted victim. The most common targeted victim in spear-phishing attack is the high ranking employees and it is very hard to protect all users from the attackers.

Some of the challenges in Spear-Phishing: It is an on-going illegitimate activity in the cybercriminal, hacktivist and nation-wide attackers' cache. It is an inexpensive and effective method to implant different forms of malware, collect user credentials, bring unexpected users to malicious websites, mimic trusted persons and organizations, and harvest valuable information about the targeted organization. Many users are deceived by spear-phishing emails (Moon et al, 2015) on believing the attackers consistently.

Man in the Middle Attack

In this type of attack, two original parties involve in communication normally in an unsecured wireless network. The sender does not know the receiver is an attacker trying to modify the message before retransmitting to the original receiver. Hence, the attacker has a control over the communication. For instance, Wi-Fi in the organization is unsecured; an attacker may intercept any information being transmitted from the employee's system. It can be prevented by installing Virtual Private Network [VPN] in employee's system, still there is a risk if the information is being captured from personal devices such as mobile phones and tablets.

CYBER ATTACKS BASED ON SECURITY PRINCIPLES

Cyber attacks are the activities executed by the cybercriminals to break the fundamental principles of cybersecurity (Liu et al, 2012) in the internet world. Cyber attack is a special form of cybercrime that accomplishes crimes/attacks in cybersecurity. The different forms of cyber attacks based on the cybersecurity basic principles are discussed below:

Attacks on Confidentiality

The various types of attacks based on confidentiality are as follows:

Traffic Analysis

In this type of attack, the attacker tries to analyze the information which is transmitted between the sender and the receiver without tampering it. It is a kind of passive attack and the attacker analyses the information to interpret some new information by stealing the confidential data. It results in violating the confidentiality principle of information security.

Eavesdropping

It refers to the activity of listening the confidential conversation secretly. The intruder track and capture the information which is transmitted between the sender and the receiver. It is similar to traffic analysis, whereas the intruder can sniff the information that can be read later according to their interest.

Snooping

It is a kind of passive attack, where the intruder tries to find the confidential information about users by hacking the personal details such as online banking, social apps, login credentials of email etc. The government officials or the corporate sector exploit the snooping methodology for monitoring the employees' activities. Snooping is categorized into two types as given below:

1. **Digital Snooping:** It is the process of tracking the private or public network to know some confidential information such as data or password. This type of attack is done at the network layer via the physical cable. The attacker may alter the network devices such as switches to acquire the

information passing in the network. To avail the organization data as authorized users, the attackers can hack the organization security cameras to obtain the username and password of employees.

2. **Shoulder Snooping:** It is a kind of physical attack where someone watches the typed password or information displaying in the monitor for that they don't have any access.

PASSWORD ATTACKS

These types of attacks are used to obtain the username and password of desktop, laptop, website or any other applications of authorized users. The retrieved username and passwords are used to get enter to network services as authorized users and to perform malicious activities. The success of this password attack depends on users password strength. If the chosen password is not weak, it is difficult for the hacker to get access to the authorized user's password. The types of password attacks are discussed below:

Dictionary-Based Attack

The attacker tries the possible combination of characters or words as given in the dictionary to hack the password of internet applications of legitimate users. The success of this attack depends on the strength of authorized user's password. If the chosen password is not available in the dictionary, then this type of attack is almost impossible to be performed by the attacker for hacking the password of the user.

Brute-Force Attack

It is a tool to hack the user password by trying all possible password combination. It is a time consuming activity based on the strength of password. However, it results in obtaining the authorized user's password.

Password-Guessing Attack

In this attack, attackers guess the password of legitimate users by using some common words such as name, date of birth, religion and so on.

Keylogger

It is a kind of malware that executes in the hidden mode on the system background, the user is unaware about the execution of keylogger. It may be in the form of icon, quick launch, entry on desktop, all programs and so on in the computer system. The information typed by the user is scanned by the keylogger and that will be transferred to the attacker without user's knowledge (Solairai et al, 2016).

Social Engineering

It is kind of attack that focuses small set of internet users and revealing information of authorized users of an individual or an organization (Krombholz et al, 2015). The types of social engineering attacks are given below:

Phishing

In this attack, the attacker tries to trick the users for hacking sensitive information such as credit card details, bank user id/password. Fake websites, emails are used by the attacker whereas it looks same as the original and it covers small to large set of network users (Mohammad et al, 2014). The various categories of phishing attacks are described below:

DNS Phishing

It is a process in which the attacker modifies the host files on victim's system or DNS database hence the legitimate web URL is modified as a fake URL. By assuming the fake website as original, the users start to feed the confidential information in an unauthorized site. Sometimes, technically strong persons also fail to differentiate the authorized and fake website (Chaudhry et al, 2016).

Spear Phishing

In this type of attack, the attacker searches for the available public information of the target via social networking or web sites. Subsequently, an attacker creates malware exist email to earn the victim's trust. Then this mail is forwarded to some set of targeted people and if anyone clicks on it, they will become as the victim. An attacker will hack the confidential information because the malware attached email works automatically when an email is opened.

Dumpster Diving

Attacker seeks confidential information of an organization or the network user without any use. For instance, the attacker searches the trash of an organization to get some sensitive information (Lau et al, 2015).

Baiting Attack

In this attack, the attacker sets the malware infected storage device at the place where the victim may notice in future. The storage devices are labeled in such a way of increasing the curiosity of target and once the storage media is accessed, the computer system will become as a victim of the attacker (Krombholz et al, 2015).

Waterholing

In this attack, an attacker indirectly targets the victim by infecting the websites where the target frequently visits. Hence the target's computer device will get affected and the attacker starts stealing the confidential details (Krombholz et al, 2015).

Reverse Social Engineering

The attackers represent themselves as trusted persons to the victim and they believe that the attacker is a trustworthy person to share the confidential details.

ATTACKS ON INTEGRITY

The different types of attacks to disrupt the integrity as follows:

Salami Attacks

Set of minor attacks that altogether result in the form of larger attack. For instance, deduction of less amount of money from the bank account is not noticeable. Once it becomes huge, it spoils the image of the bank.

Data Diddling Attacks

It is an activity of illegal data modification. For instance, account executives alter the timesheet information of employees before reaching the payroll application.

Cross-Site Scripting (XSS)

Attacker inserts malicious script into vulnerable websites or applications that the target visits. The hacker's malicious code is automatically transferred to victim's browser, once the target visits the vulnerable website. The malicious code accesses the sensitive information from the victim's browser (Kieyzun et al, 2009).

SQL Injection Attack

It is similar to cross-site scripting rather it uses the vulnerabilities of SQL statement. It affects the websites, web application database and the information in the database is revealed to the attacker (Kieyzun et al, 2009).

Session Hijacking Attacks

Attacker modifies the session among two or more authorized users to gain the authorized access of information. Example: Man-in the middle attack, TCP Session hijacking.

Attacks on Availability

It refers the process to disrupt or stop the availability of required resources to the authorized users. The few common attacks are described below:

DoS/DDoS

Denial of Service (DoS) is an attack that interrupts the availability of network resources. The victim can be targeted either directly or indirectly. In direct attack, the hacker creates huge traffic by using the own computer system, while in indirect attack, the hacker hacks another system refers as "bots" to create the traffic for the victim. In DDoS, huge number of bots or a server can be used to disrupt the network services such as system resources, application resources, and network bandwidth (Zlomislic et al, 2014; Osanaiye et al, 2016). The various consequences of DoS attack,

- Slow network performance
- Unavailability of network services

The different types of Dos/DDoS attacks are discussed below:

TCP SYN Attack

In this attack, attacker utilizes the loop-hole of the three-way handshake process during the connection establishment of TCP (Transmission Control Protocol).

Steps in three way handshake protocol:

1. Client sends SYN (Synchronization) request to the server
2. Server gives response with ACK (Acknowledgement) to the client
3. Clients, in turn respond with final ACK

Attacker broadcasts SYN requests and never transmits the final ACK which leads to overflow of the target capacity results in unavailability of network resources (Pan et al, 2006).

UDP Attack

TCP and UDP [User Datagram Protocol] are the transport layer protocol in TCP/IP model. TCP is reliable, connection-oriented protocol and UDP is unreliable, connection-less protocol. In connectionless, reliability can be compromised to some extent and the attacker generates huge amount of UDP packets to overflow the response handling queue which leads to unavailability of network resources to the users (Pan et al, 2006).

ICMP Attack

ICMP (Internet Control Message Protocol) is a network layer protocol used by network devices such as routers to generate the error report if any problem is encountered during delivery of IP packets. Attacker generates the huge traffic of ICMP traffic to the targeted host which automatically consumes the bandwidth.

ICMP attack can be done in two ways:

1. Ping of death attack
2. Smurf attack

Ping of Death Attack

It is a mechanism to check the availability of particular IP packets using small packets. Attacker sends large-size packets than the maximum packet size. The target may crash or reboot though it is not configured with the large-size packets.

Smurf Attack

1

It follows the amplification strategy and it targets the Internet Broadcast Address (IBA) which is in IP protocol. Attacker sends request by spoofing the address of the target to IBA of the intermediary node reply with amplified response to the target node. The intermediary response is broadcasted to all hosts and IBA can support upto 255 hosts. Hence, the smurf attack amplifies a ping 255 times (Barnett et al, 2000).

HTTP Attack

HTTP (Hypertext Transfer Protocol) is an application layer protocol of TCP/IP model. The web applications and services use HTTP packets such as GET and POST request. Hackers transmit huge amount of GET or POST request to the target host results in overwhelming the target capacity (Barnett et al, 2000).

CYBERCRIME STATISTICS

Most of the cyber-attacks are focused against only small scale businesses. According to Cybersecurity Ventures Prediction, victim to a ransomware attack increases from every 40 seconds in 2017 to every 24 seconds by 2019. In the past 2 years, it has been recorded that the ransomware damages up to 15X and it is expected to quadruple by 2020 in healthcare organizations. FBI's BEC (Business Email Compromise), Internet Crime Complaint Center (IC3) the total amount of loss has been increased 1,300 percent since January 2015 at more than \$3 billion. According to the CISCO's, BEC has viewed the identified exposed losses totaling over \$5 billion from 2013 through 2016, and the losses persist to mount. According to the global survey conducted previous year by the Microsoft Digital Crimes Unit, 2 out of 3 people have experienced the technical support scam in the last 12 months. The cyber criminals are generating around 1.4 million phishing websites with fake pages to impersonate the targeted company which they're spoofing. The distributed denial-of-service attacks are 4X larger than the status before two years – it is about 42% of DDoS incidents in 2017, from 10% of cases in 2015. Cybersecurity Ventures anticipates that recently reported zero-day exploits will mount from one-per-week in the year 2015 to one-per-day by 2021. According to the study report of 2018, the distribution of attack techniques are depicted as shown in the Figure 5.

IMPACT OF CYBERCRIME ON SOCIETY

Cybercrime has become a major threat for the persons using internet, millions of information are being stolen within the past few years (Jang-Jaccard et al, 2014). The global cost of cybercrime may reach \$6 trillion by 2021 in an economy era. According to the study of Data Breach Study of Ponemon Institute's 2016, Global Analysis organizations that experienced one breach in 2016 lost an average of \$4 million. 48% of data security breaches are caused due to malicious activities. Cybercrime will triple the number of unfilled cybersecurity job opportunities by 2021.

Figure 5. Distribution of attack techniques

Cyber Crime Security

Securing IT infrastructure and countermeasures for various attacks are mandatory as the cyber attacks are increasing every day due to technology advancement. Cyber security is a potential activity by which information and other communication systems are protected from and/or defended against the unauthorized use or modification or exploitation or even theft. Likewise, cyber security is a well-designed technique to protect computers, networks, different programs, personal data, etc., from unauthorized access (Razzaq et al, 2013). Although finding out the countermeasures for these attacks are not easy and its quite complex because of a number of layers of defense. Developing a single suite for managing all these attacks is very difficult due to the existence of several layer of defense (Barnett et al, 2016). The ratio of threat is increasing as the probability of risk is also increasing day by day and organizations should consider the information security as the primary concern.

None of the small, medium or large organization around the world is completely safe since the cyber attacks happen every second. Nation-wide attackers and cyber attackers gives the biggest information security threat around the globe. According to the report of Center for Strategic and International Studies (CSIS), cybercrime expenses the global economy on \$445 billion and the harm to businesses from attackers stealing intellectual property exceeds \$160 billion every year. Based on the study over 15 million attacks gathered throughout various news and events, FBI (Federal Bureau of Investigations), CISCO, Cenxic, FireEye, Kaspersky, Verizon, Mandiant, Sophos and Syumantec, the cyber-attack is an on-going trend, strengthened by hacker's efficient tools and strategies by hiding their presence for obtaining sensitive information.

According to the report, "Attacks on IoT devices increases rapidly because of weak security hygiene, exponential growth in the amount of connected objects, and the huge volume of data in IoT devices" and it is anticipated that by 2019, the devices connected to the internet will be 50 billion. The new strategies are continuously developed by the attackers to exploit the data and network. Some study reveals that the root-cause of security breaches in 50% of criminal intended attacks are based on three significant factors: system vulnerabilities, human error and intended attack (Liu et al, 2012). Basically, there are two categories of cyber crime security measures that are viewed as external and internal.

External

Many nonprofit organizations are combating against cyberattacks, International Association of Cyber-crime Prevention (IACP) or Secure Domain Foundation (SDF) are assisting to be aware of attacks, risks and states how to defend against attacks. Moreover, Google recently forms a team known as Project Zero to mitigate the cyber-attack risk and to analyze the bugs, vulnerabilities by taking the necessary steps for improving the software products. Cyber-attacks also entered in financial institutions, AXA Corporate Solutions is a financial company launched an insurance product covers the expenses to recover after some errors or accidental events, viruses and cyber attacks. Additionally, another product is also launched for assessing and mitigating cyber risks. The legal approach is the most essential aspect regarding cyber crime and security. Although the laws and regulations are constantly developed to limit or prevent the cyber-crime activities, however these set of laws and regulations are geographically limited to certain level.

Internal

Continuous Risk Assessment

Every organization should implement the security controls and the necessary steps should be taken to identify threats, vulnerability and risks. IT based companies should ensure that all hardware, software including protection software (i.e. antivirus program) is always updated with the latest patches. Moreover, the agreement is mandatory for companies in place of third party to cover the maintenance and upgraded services.

Authentication

Focusing on the risk assessment, the organizational data is solely protected using the password technique. For remote or web-based applications, complex authentication strategies are recommended to use. For instance, combining password and biometric authentication is a complex authentication mechanism.

Internal Commitment and Responsibility

Risks are more often in the organization premises than expected, some security breaches can be caused even unintentionally by the internal users. Hence, formalize the set of policies, procedures in a concise manner by well documenting the controls and processes assist in maintaining and enriching the information security.

Access to Information

Organizations should always ensure that the privilege is properly restricted and the session for outsiders should be correctly disabled who has connection to the company's network. A wide range of risks, addresses various issues from manual to automated controls. Manual control can be accomplished by conducting the periodic review of access rights for all users and with the automated control, the domain account is automatically terminated once if it is not connected for a certain amount of time.

Data Retention

Removing all data if no longer required, in such a way compromising information security policies can be avoided. The data archive should be maintained as long as it is required on a secured environment (back-up servers) and eradicated from the organization's network, therefore limits the unauthorized access to sensitive data. The study revealed that 20% of stolen information was the data without any evidence in the company's network.

Threat Intelligence

There are numerous ways to collect threat intelligence. For instance, the intelligence can be purchased directly from security vendors in a report format. And there is a possibility to join in an intelligence sharing group such as financial service industry's (FS-ISAC) to know about the threat. Intelligence can also be retrieved by own by examining the incoming connections in the network. Intelligent gathering process is an on-going process in many organizations to widen the threat intelligence capability. Hence, combining intelligence into a single source plays a vital role in security related operations.

Minimize Delivery of Malware

Social engineering is the most common strategy to reduce the malware or threat introducing vulnerabilities. There are numerous ways to allow the threat in an organization, such as phishing or leaving USB in the company premises and unintentionally it may lead to some harmful action.

Organizing information security related programmes very often in an organization assist in creating awareness about security breaches. Advance technical controls are existing nowadays; even though human resource is considered to be the main source in spreading malware. By using registered software's on all computers, the chances for the threat of cyber attack can be extensively reduced. Corrupted or Pirated versions are the main reasons for introducing malware in the network.

GUIDELINES TO DEFEND CYBERCRIME

In the modern age of technology, no one is safe and secure in the internet world. The average dwell time is considered to be more than 200 days for a company to detect the cyber breach. Moreover, the internet users do not believe in the fact that they may get attacked of not updating the passwords or other credentials frequently. It gives the opportunities for hackers to perform cyber crime activities. The ways to prevent execution of malware are least access privileges, application white listing, Identity and access management, Network restrictions/segmenting to be strictly followed. The life cycle of preventing cyber crime is illustrated in Figure 6.

Identify the hackers immediately once they enter in IT infrastructure. Protect the environment by maintaining updated versions and detect the malicious activity done by the attacker (Ali et al, 2015). Provide the fast response and recover from the scenario to continue the process without any disruption.

Figure 6. Steps to prevent cyber crime

Authorized users should be aware on the preventive measures to protect the individual as well as the business sector. Some significant strategies to be followed for preventing cyber crime,

1. Be vigilant when surfing websites
2. Choose VPN whenever possible
3. Make sure the websites are safe before entering credentials
4. Maintain antivirus or application systems up to date
5. Strengthen the password, never use weak password
6. Flag and report suspicious emails
7. Never click the unfamiliar links

CONCLUSION

The world is facing a massive problem in ensuring the proper security of information. To handle the problem due to the exponential growth of cyber crime is a world-wide awareness, from an individual to organizational perspective in the cyber world. Probably, the legal aspect is the main barrier in every state or region which has their own set of laws and regulations governing the attack of data privacy and theft. Internet is acting as the most powerful tool for the attackers in cybercrime. The only possible way to defeat the cybercrime is to think and act globally regarding the safety and rights of citizens in the whole world.

A Survey on Emerging Cyber Crimes and Their Impact Worldwide

1

Suraj Gangwar*University of Delhi, India***Vinayak Narang***University of Delhi, India*

INTRODUCTION

Cybercrime is an unlawful act wherein the computer is a tool or target or both. The number of cybercrimes has escalated in recent times. The opportunity for cybercrime is increasing with the increasing number of internet users. In the year 2016, it was reported as the second most commonly reported crime across the world. Report published by World Economic Forum placed cybercrime in top five of the global risk for 2018 (The Global Risks Report 2018 (13th Edition), 2018). The reason behind is simple: the rate of internet connections and the ever growing number of computer devices are outpacing our ability to properly save them (Security Predictions for 2018 Paradigm Shifts, 2017). In today's increasingly connected digital world, organisations are too hyper-connected with a new wave of technologies to improve their performance. At the same time cyber-attacks are becoming more sophisticated and impactful (Cybersecurity Regained: Preparing to Face Cyber Attacks, 2017). Embracing of technical innovations such as the Internet of Things (IoT), cloud computing and AI/ML, by organisations provides cybercriminals with new avenues for attack.

As per a report generated by Global Cyber Security Index (GCI), it can be inferred that majority of the countries in world are not yet ready to deal with cyber-attacks. GCI categorizes the countries depending upon their level of cyber security. It divides the countries in three stages

1. Leading stage: which includes countries that show high commitment to face cyber-attacks
2. Developing stage: which includes countries that are increasingly digitized but are still developing their cyber security capabilities
3. Initiating stage: which includes countries whose economies are only beginning to be digitized and where cyber security efforts are just a beginning.

The 2017 report reveals that only 21 countries are at a leading stage and 96 countries are still at the initiating stage. So there is still much needed to be done to tackle cybercrime menace efficiently (Global Cybersecurity Index (GCI), 2017).

BACKGROUND

The Internet connection was available to general public in 1989 and the first ever website was launched in 1991. Today, there are more than a billion websites and the number of internet users is increasing with each passing day. Figure 1 shows exponential growth of the internet users from 1995 to 2017. There will be 6 billion internet users by 2022 which equals 75 percent of the estimated world population of 8 billion. This prevalent and dominant nature of computers and internet in our life has made cybercrimes more prominent (Morgan, 2017).

The first cyber attack took place in 1988. Morris Worm (named after its creator) infected thousands of computer systems and it took almost 72 hours to halt it. Nowadays these kinds of attack are frequent in numbers (Shackelford, 2018). The growth in importance of cyberspace across the globe has enabled vectors for, and broadens the scope of many existing forms of cyber-attacks. On one hand, cyberspace facilitates globalization of businesses and on the other, it has become a global platform for committing crimes. Individuals or more specifically cybercriminals from across the globe are using this environment to attack critical infrastructures, government and private businesses by stealing, compromising the integrity of, and destroying the data. It has created new marketplaces and even the trafficking and exploitation of human and gives a privilege for the creation and exchange of solicitation and sexual exploitation related materials (Emerging Trends In Global Cyber Crime, 2017). Cybercrimes are diverting from traditional to newly advanced crimes that can create the hoax in the world for example the Petya ransomware paralyzed the biggest container port in Mumbai, India; the cybercriminals breached the presidential election campaigns in France and USA (Cybersecurity Regained: Preparing to Face Cyber Attacks, 2017). Cybercriminals are fueled primarily by economic motives and non-economic motives. Crimes done with economic motives may include cheating, credit card fraud, money laundering, cryptojacking etc. Crimes done with non-economic motives may include cyberstalking, cyberbullying,

Figure 1. Growth of internet users from 1995 to 2017

Source: <https://www.internetworldstats.com>

cyberdefamation etc. In order to understand the world of cybercrime, there are terms which are required to be defined. Some of them are:

1. **Botnet:** Group of computers connected to internet which are compromised by bots for malicious intent, usually DDoS Attack.
2. **Computer Virus:** A malicious software loaded in a user's computer, when executed, has the capability to damage the files and replicate itself. In order to damage and infect other executables, it attaches itself to an existing program.
3. **Computer Worm:** A type of malware that spreads by replicating itself from computer to computer. It uses a network to spread itself due to inadequately protected computers and the servers on the network. It doesn't need a host program to run.
4. **Cyberbullying:** It is the use of cyberspace to bully or harass someone.
5. **Cyberstalking:** This occurs when internet is used to harass or frighten where the user is subjected to a plenty of online messages and emails.
6. **Cyberdefamation:** This occurs when defamation takes place using computers and/or internet.
7. **Distributed Denial of Service Attacks (DDoS Attacks):** They make an online service unavailable and take the network down by overwhelming the site with traffic from a variety of sources.
8. **Identity Theft:** This cybercrime occurs when a criminal is misusing personal information after gaining access to it.
9. **Malware:** A malware is a computer software designed to disrupt, damage or gain access to computer or computer network.
10. **Phishing:** This cybercrime aims at using email messages to get personal information from users.
11. **Spyware:** Spyware is a type of malware installed on a user's computer often without his knowledge, designed to gain access to steal sensitive information or damage your computer.
12. **Spoofing:** It is a malicious practice in which a person or programs impersonates and attempts to gain unauthorized access to a user's system or information.
13. **Trojan:** A Trojan horse or Trojan is a type of malware which disguises users of its true intent. It is used to gain access to the target computer.

Focus of the Article: Emerging Trends in Cybercrime

According to Interpol “*New trends in cybercrime are emerging all the time, with an estimated cost to the global economy running to billions of dollars*”. In the past cybercrimes were committed mainly by small groups or individuals. Today, there are highly complex cyber criminals' organizations that have individuals from all around the world to commit crime at an unprecedented scale (Interpol). Cyber criminals on the web keep track of cyber security trends and react to them by modifying viruses, exploits and other methods to beat the safety nets. Traditional attacks are dependent on a lot of intermediary factors in the overall attack chain which is subject to detection by firewalls, antivirus, and intrusion detection systems. This has led attackers to use advance techniques to avoid detection and/or bypass defenses (Zimba, Wang, Mulenge, & Odongo, 2018).

There is a growing trend of highly targeted attacks, in which criminals manually break into a company computer, disable or evade internal security tools, and launch malware on whole networks of machines, all at once (SophosLabs 2019 Threat Report, 2018). Another growing trend is the use of cyber-attacks to target critical infrastructure and strategic industrial sectors that raise fears, in the worst case scenario, the attackers could trigger a breakdown of societal systems. Stuxnet malware attack is an example of

such attacks (Falliere, Murchu, & Chien, 2011). Emerging attacks are well thought-out and focus on new attack vectors and vulnerabilities enabled by technologies for example: exploiting vulnerabilities on smart devices to gain access to data and control systems. Not only this, cybercriminals are spending a lot of money for specific research to find exploits and vulnerabilities.

The cyberbullying has reached to a whole new level where harassed people are committing suicide. In 2017, there was a rumor of online game named BlueWhale or BlueWhale Challenge which challenged its participants/victims to do a series of tasks with the final task to commit suicide by beaching whale in the hand, caused unrest worldwide. According to Cyberbullying Research Center, between October 2016 and April 2017 there were 232,000 BlueWhale hashtags in Russia which the social networking site Vkontakte identified that bots (not real people) were using those hashtags, implying that the game started with fake news and eventually it went live (Patchin, 2017). Cybercrimes are not always new but they evolve in accordance with the opportunities presented online. Here are the some emerging areas of cybercrimes which are reshaping the traditional cybercrimes.

Crypto Mining: Cryptocurrencies popularity reached an all-time high when Bitcoin values increased by over 1300 percent and reached a record US \$ 19,783 per coin in 2017 at one point. They have become hot new investments for investors and fortune hunters. But they are not only ones interested in them. Cryptocurrencies have become a major point of interest for cyber criminals, as they present a perfect opportunity for them in various aspects (Sigler, 2018). There has been seen a major shift in cyberspace toward the use of cryptocurrencies for proceeds of cybercrime activities because they are easy to transfer and carry a low risk of catching the criminal(s) (Zimba, Wang, Mulenge, & Odongo, 2018).

Crypto mining, the process of generating the cryptocurrency, requires the use of computational power to solve complex mathematical equations as proof of work. It requires a lot of CPU resources. To overcome this issue, cybercriminals use crypto jacking which is running a mining script on someone else's machine without their knowledge or permission to illegally mine cryptocurrency. Crypto jacking has become an ideal venture for criminals because it is easy to deploy and safer to perform on target machines. Two most common attack approaches used by cyber criminals are crypto mining based on the web browser which leverages JavaScript, and installable binary crypto mining where the malware is running in memory (Zimba, Wang, Mulenge, & Odongo, 2018). High-traffic websites are the most popular choice for crypto mining operations, as a higher number of active users generate currency more quickly. Early in 2018, a malware known as Smominru was found to have compromised half a million machines for crypto mining (Sigler, 2018). In September 2018, the Economic Times (ET) revealed that Indian government websites were not spared this phenomenon, stating that widely-trusted Indian portals had been exploited by the crypto jacking menace (Christopher, 2018).

Advanced Social Engineering: Computer network security today maintains sufficient robustness and sometimes even automated vigilance experienced hackers are no longer seeking to replace social engineering but rather see it as an integral part (perhaps the most important part) of any successful toolkit for hackers (Mitnick & Simon, 2002). In fact, some observers now call social engineering "the highest form of hacking" (Greiner, 2006). Kaspersky Labs defines social engineering as a form of techniques employed by cyber criminals designed to lure unsuspecting users into sending them their confidential data, infecting their computers with malware or opening links to infected sites (Kaspersky Lab).

It is a technique that distinguishes one variant of social engineering attack from another depending on the specific form of the attack as impersonation is an attempt to gather authentic information to gain access to a targeted network; third party authorization occurs when authentication details are stolen by or given to the third party; phishing emails are an attempt to trick the recipient into performing some action, usually clicking on malicious link or downloading an attachment, it tends to be the most diffi-

cult social engineering tactics to detect as sophisticated attackers can often send emails that look same to real ones; internal social engineering happens when a system administrator uses social engineering techniques against their own organizations to identify individuals who represent weak nodes in the network; reverse social engineering is said to occur when instead of attacker initiating contact with the victim, the reverse occurs i.e. the victim is tricked into initiating the contact themselves; automated social engineering attacks use botnets, algorithms and automated programs to perform many of the social engineering attacks that used to require skilled interaction between attacker and victim, and semantic attacks are an attempt to seek to deceive rather than directly attack a victim through the manipulation of object characteristics (Hatfield, 2017).

During the 2016 United States Presidential election, the chairman for Hilary Clinton's campaign John Podesta was sent an email that appeared to be legitimate Google Mail containing security warning caused due to suspicious activity involving someone attempting to log in to his account from Ukraine. The e-mail asked that Podesta change his password immediately and helpfully provided a link for him to do so. The campaign's IT help desk couldn't check the authenticity of the e-mail and they notified that he should change his password immediately which led to hacking of his account (CBS News, 2016).

Attacks on the IoT: According to Intel, there will be 200 billion smart devices or IoT devices by 2020. ABI has forecasted that more than 20 million connected cars will ship with built-in software-based security technology with 2020 and Spanish telecom provider Telefonica estimates that by 2020, 90 percent of cars will be online compared with just 2 percent in 2012. Gartner has predicted that more than half a billion wearable devices will be sold worldwide in 2021, up from roughly 310 million in 2017. Wearable include smart watches head-mounted displays, body-worn cameras, Bluetooth headsets and fitness monitors (Morgan, 2017).

David Wall speculated back in 2007 that the fourth generation of technology might be oscillating between completely virtual crime taking place in the virtual world or ambient crime (targeted at Ambient Intelligence, or Internet of Things), it is increasingly becoming apparent from above numbers that it will be the latter (Wall, 2007). Society is becoming more vulnerable due to introduction of autonomic devices and its move towards interconnecting everything by using internet as the medium; these vulnerabilities are bound to be exploited by criminals and terrorists. The interconnected advantages and accessibility involved in the IoT means that cyber criminals would likely be interested in ways to compromise this channel. Businesses will be more vulnerable to these attacks if they use IoT for security of building or any other back-end processes. The threat on IoT may even be to life as everything is getting smart from bulb to car, imagine the case when the criminals getting access to controls of support systems in hospital or taking control of connected cars on road. In 2016, the Mirai malware attack took advantages of vulnerabilities of IoT devices, infecting thousands of devices like unprotected webcams, TV networks and other smart devices. This allowed hackers to launch a DDoS attack (Internet Security Threat Report, 2017).

Other Crimes: Cyber criminals always find new and complex ways to commit crimes in order to achieve their objective which can be monetary gain or other reason. And getting hands on the sensitive data of big organization can be worth a fortune for attacker. So he tries to gain access to any organization's database that may contain sensitive information about their customers, employees or any Personally Identifiable Information (PII). **Data breach** is an incident where information is stolen or extracted without knowledge of system's owner. Data breaches are almost every day in the news. Technology giants such as Facebook and Yahoo have not been able to save themselves from data breaches. In 2014, 3 billion user profiles were compromised in Yahoo's data breach, largest in the history till date. According to reports, 4 billion data records of various kinds were stolen in 2016. In 2018, Facebook has been in the news for a high profile data leak. The data stolen from Facebook was being used by Cambridge

Analytica to manipulate the human behavior using techniques like artificial intelligence and machine learning. In November 2018 the hotel chain Marriott announced the massive data breach of its 500 million customers (Time, 2018). Figure 2 shows the biggest data breaches in the history.

Digital wildfire is another cybercrime that is creating buzz globally. Digital wildfire can be defined as spreading of the misinformation rapidly over the internet. They can rip through public at breakneck speed and can cause social and economic unrest in the world. In 2018 Facebook disclosed that Russians with fake names used the social network to try to influence United States voters during the 2016 election by spreading false information. The Guardian has reported that the Russian president, Vladimir Putin, has spent more than £1 billion a year to for spreading fake news. In addition, there is troll factory (company set up in order to post comments and messages to influence people) based in St. Petersburg, Russia primarily for spreading fake information, sending spam messages and causing DDoS attacks (The Guardian, 2018).

The Evolution of Malware

Malware, the broad term for any type of malicious software that can harm computers, is a major problem. And it's getting bigger and worse, promising to poison everything from home appliances to national politics (The Evolution of Malware). A data infographic compiled by cyber security solutions firm RSA noted that one in every twenty malware attacks around the globe involves the use of ransomware (Emerging Trends In Global Cyber Crime, 2017), a type of malware in which the attacker encrypts the data and/ or blocks the computer access by the victim and demands money in return to restore functionality. There is a new emerging trend in malware: use of publically available and tested exploits like Eternal Series (developed by National Security Agency, USA) to create malware for increasing the chances of successful attack (SophosLabs 2019 Threat Report, 2018). One such example is Petya ransomware which uses Eternal Blue and Eternal Red exploit as a weapon to propagate in compromised machine network. Deploying malware on a multi-national scale is simple as WannaCry showed us (Emerging Trends In Global Cyber Crime, 2017). Today's malware are mostly machine-driven. But criminals are moving towards manually deployment of malwares to increase the chances of achieving their goal. The cyber

Figure 2. Biggest data breaches in history

Source: <https://www.statista.com>

criminals are also using *multi-intent* malware to attack target machines. Multi-intent malware starts by executing a malicious intent and once it has maximized the revenue from that channel, it moves onto another. It does this until it completes all the malicious intent it was programmed to execute. XBash is an example of multi-intent malware. It not only included ransomware, botnets and worms but also ability to reconnaissance (Darkreading, 2018).

As there is a greater degree of success to get hold on the ransomware attacks, the attackers are targeting to such victims and devices that have the capacity to pay greater sums and are new in the market and have security flaws, respectively (McAfee Labs 2018 Threats Predictions Report, 2017). A business will fall victim to a ransomware attack every 14 seconds by 2019 up from every 40 seconds in 2017. Ransomware attacks on healthcare organization are expected to quadruple by 2020 (Morgan, 2017). One such attack on the Dyn DNS provider brought internet to a pause, deranging tech giants like Twitter and Spotify amongst others (Cybersecurity Regained: Preparing to Face Cyber Attacks, 2017).

While malware that runs on the Windows operating system still outnumbers malware for any other platform (SophosLabs 2019 Threat Report, 2018), malwares are making their way from PCs to mobile phones as they have become an essential part of people's life and certainly contain a massive amount of personal information from photos to banking details. Users of mobile devices are subjected to malware integrated applications to their phones, tablets, or other devices with Android and iOS operating system. The most well-known is SMiShing, which tricks clients into uncovering individual data and passwords (Smishing - Text Messaging Scams). Malware's unpolished effectiveness implies its reach will keep on growing exponentially.

Impact of Cybercrimes

Main impact of cybercrimes are monetary losses. But there are other impacts which are not measurable but they can lead organizations to shut down. The stakes are higher as the organizations falling prey to cyber-attacks are at risk of reputational and as well as consumer loss.

Economic Impact: The 2017 Norton Cyber Security Insights Report disclosed that in the year 2016, 978 million consumers were affected by cybercrime and the total financial cost of cybercrime was US \$172 billion globally (2017 Norton Cyber Security Insights Report, 2017). An estimate put the economic impact at US \$445 billion worldwide, and about 15-20 percent of value is created by the internet. In many cases, the estimate on economic losses can be misleading. This is because too many companies still fail to quantify the losses related to cybercrime. In some cases, they are completely unaware that they are the victim of attack. Most numbers are based on a survey and loss estimates are based on raw assumptions of magnitude and effect. Cybercrime is more profitable than the global trade in marijuana, cocaine and heroin combined as cybercrime victims lose about US \$290 billion each year according to global estimates (Aiken, Mahon, Haughton, O'Neill, & O'Carroll, 2015). According to Center for Strategic and International Studies (CSIS) and McAfee report named Economic Impact of Cybercrime- No Slowing Down the global estimate suggests that as a percentage of global GDP, cybercrime cost the global economy 0.8 percent in 2017 (The Economic Impact of Cybercrime- No Slowing Down, 2018). The scale of the threat is expanding drastically: by 2021, the global cost of cyber security breaches will reach US \$6 trillion by some estimates, double the total for 2015 (Cybersecurity Regained: Preparing to Face Cyber Attacks, 2017).

Cybercrime is doing unmatched damage to both private and public enterprises and driving up IT security spending. Cybersecurity Ventures Report 2017 predicts 12-15 percent year-over-year cyber security market growth (Morgan, 2017). Today everyone has become highly dependent on computer and

networks for storing and preserving information, as a result, the risk of being subjected to cybercrime is huge. The CIA triads (Confidentiality Integrity Availability) of computer systems are continuously attacked by cybercriminals. According to surveys done in the past, 80 percent of the companies' surveyed acknowledged financial losses due to data breaches. The approximate number impacted was US \$450 million. As the economies are racing towards digitalization, they are exposed to all the threats posed by cybercriminals. Financial transactions are performed via the internet, payments are made by credit cards via the internet, and stocks are traded via the internet. Every fraud in such transactions, detrimentally affects the company's reputation and productivity thereby causing financial losses. Today in the era of globalization one region is dependent on another. Hence the disruption of financial market of one region could have a ripple effect in other regions (Saini, Rao, & Panda, 2012).

Impact on National Security: When it comes to national security, the impact of cybercrime can be huge. Almost every entity of a nation be it government, private organisations, individuals all depend on internet in some way or the other. The attack can affect an individual or an entire nation, whatever may be the case it would undermine the confidence of people for the government in motion.

Militaries of most of the countries rely heavily on advance computing with all almost all resources digitally connected, even the nuclear weapons. This could turn the prediction of cyberwar into reality. Cyberwar refers to the use of digital attacks like computer viruses and use of malicious codes by one country to disrupt the important computer systems or networks of another, with the aim of creating damage, death and destruction. It will see hackers using codes to attack an enemy's infrastructure, fighting alongside troops using conventional weapons like guns and missiles (Ranger, 2018). It has potential to disable, damage and destroy military systems, space systems and can push back civilization decades back. In order to avert this disaster it is very important for nations to secure their digital space in a robust manner, thus securing the nation.

Impact on Consumers: Companies attacked by cyber criminals could have a huge impact on consumer trust. As the concept of e-business and e-commerce is dominating the market, more consumers are doing activities like shopping, banking etc. online. Visiting the concerned page which is subjected to cyber-attacks, discourage the consumer from using it on a long-term basis. As most of the consumers are unaware of the third party involvement (more specifically cyber criminals) in the crime, so they call the compromised site fraudulent. This makes consumer not only lose trust in the e-commerce but they altogether lose confidence in using the internet for various other purposes (Saini, Rao, & Panda, 2012). A survey revealed that 63 per cent people believe it's harder to stay safe online than in the real world (2016 Norton Cyber Security Insights Report, 2016).

SOLUTIONS TO PREVENT CYBERCRIMES

Cybercrimes continue to grow rapidly at an ever increasing pace. When one hears and reads about the range of cybercrimes out there, an individual might be tempted to stop using the internet entirely, but that is not the solution. Instead, it is better to be aware and take precautions to help protect against it. Some of the basic measures that can be employed at the grassroot level are by having proper awareness about the scams that exist on the World Wide Web and the precautions that need to be taken to avert them. This can be done by keeping oneself updated through internet by following cyber awareness websites and people who research in this domain.

It is often noticed that people become victims of such crimes by clicking on links that might pose to real but in reality are phishing links. These links ask for important credentials such as username, password or in many cases would download a malware into one's system, which can prove to be detrimental. So, it is very important to be cautious enough before clicking any link, especially when the link is from unknown sources. Also, due to ever evolving nature of security breaches it is very important for an individual to keep their system's operating system updated with latest security patches. Some of the basic things that can be done at the user level are firstly, using a firewall protection, it monitors the traffic between computer and the internet and filters the malicious requests beforehand to keep the intruders at bay. Secondly, strong passwords need to be used to protect confidential data, though it is easier to remember passwords like pet's name, birthdate, personal name but they can easily be cracked. Hence, it is important to use passwords which are at least 10 characters long and consist of combination of letters (Dell). It is even better to prefix a small sentence before the chosen password this would not only make it long enough but also make it difficult to crack. Thirdly, all personal/company data should be backed up to a secondary source to be safe in case of any data breach or ransomware attack.

Businesses can review and implement standards defined by the National Institute of Standards and Technology (NIST) framework, the European Union's General Data Protection Regulation (GDPR) or any other reputed organizations to ensure security from cyber-attacks. GDPR is the set of rules governing the security and privacy of personal data and NIST focuses on publishing standards for various industries in wide variety of areas.

The most alarming issue with cybercrimes is that they are borderless, without any territory. So, it becomes very important for countries to come together and form global organizations, facilitating them to work together in catching the culprit. Mere coming together of countries will not help, instead a multidimensional approach is required wherein, IT companies, financial institutions and law organizations work in unison to tackle these issues. Also, close cooperation between public and private players is of utmost importance given the enormous risks associated with global connectivity boom. Cyber Education - Hackers aren't the only ones who can gain power from information. By educating oneself about the types of scams that exist on the Internet and how to avert them, an individual is putting oneself a step ahead of the cybercriminals. Read up on the latest phishing scams and learn how to recognize a phishing attempt.

FUTURE RESEARCH DIRECTION IN CYBER CRIMES

With evolution of technology, cybercrimes have also evolved and increased the complications and risks associated with it. Every day there is a different type of attack on a vulnerability which needs to be addressed seriously. Hence, a lot needs to be done, especially in research and development sector to find solutions to the upcoming threats, in order to be future ready and avert any upcoming cyber disaster.

One of the major area that needs to be researched upon is that of artificial intelligence (AI). It has its own merit and demerits. On one hand, it can help the organizations to defend from cyber-attacks and on the other it can be used notoriously by cyber criminals to carry out malicious activities. In this era, cybercriminals are posing never ending threats to the cyber world with new and dangerous malware, botnets and viruses, in such a scenario solutions coming with AI are promising. Advances in machine learning technology mean that AI applications can automatically adapt to changes in threats and spot problems as they arise. The pattern detection algorithms, advanced analytics, and automated alerting systems make machine learning an effective tool to fight cybercriminals (Singh, 2018)

With innovation in technology everything around us is connected to internet be it refrigerators, air conditioners, wearables, mobile phones, vehicles, computers and what not. All these devices have an operating system or firmware, which if, accessed by a hacker can create a blunder. In order to curb this foreseen havoc, proper research needs to be done on how to secure these devices. Also, the root cause of most of the cyber-attacks is the malware hence, their analysis is essential .It requires proper virtualized lab environment to study its behavior so as to contain the intrusion and stop it before it does any damage.

CONCLUSION

This paper presents an overview of traditional and emerging cybercrimes around globe and explains their impact on economy, consumer and national security. This will help the society to understand the need of tackling the cybercrimes and the ways to safeguard themselves. Understanding the behavior of people behind the screens who are committing the cybercrimes, is not an easy task but it will definitely help to find out the ways to overcome the situation.

With boom in internet usage worldwide, the cybercrime, in realities, will be growing at similar pace to real world crimes within a short span of time. The fear of cybercrimes on cutting age technology is unbound and can do potential damage to the society. Due to borderless nature of these crimes it is important for countries to come together and form organizations that work in unison for proactive research in the cybercrime area and should develop new innovative international norms keeping in mind the dynamic nature of the field. Policy making and strong cyber laws are the ways to overcome these crimes. But most of the nations are yet to work on it. Widespread awareness amongst all sections of society will help to mitigate portion of the crime. Societies and government have a vital role to play in maintaining the healthy digital hygiene but the software giants and those with ability to stop frauds are the ones who can prevent the cybercrimes and help in preserving the consumer trust on using the cyberspace. There is still lot of research to be done in the in the ways to defeat the menace of cybercrime.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: It is the area of computer science in which machines are created that have ability to think and learn like human.

Bot: It is a virtual robot created to automotive task both simple and repetitive.

Cyber: A broad term relating to or characteristic of the culture involving computers, information technology, and the internet.

Cybercrime: Crime done in or using cyberspace is called cybercrime.

Cyberspace: Cyberspace is the environment created by the links of tangible like a computer, intangible like application and services, and networks like the internet and communication.

Internet: It is a network of networks that connects millions of computers together globally. It is used for communication, entertainment, etc.

Internet of Things (IoT): IoT is a concept of connecting any device to the internet or other connected devices to send and receive data.

Machine Learning: It is the science of training the machine how to learn using algorithms and mathematical models to improve their performance.

Artificial Intelligence–Based Cybercrime

INTRODUCTION

The field of Artificial Intelligence (AI) has made swift progress in recent years, becoming much more pervasive in the lives of ordinary citizens. Many of the advances in AI have already led to exciting capabilities: intelligent agents on smartphones (Apple's Siri and Microsoft's Cortana), intelligent voice interaction devices in the home (Amazon's Echo) and countless interactive toys for children. Other upcoming advances are even more impactful, from self-driving cars to learning robots (Pinto & Gupta, 2015) and intelligent systems that automate the jobs of white-collar professionals. In fact, much has been written about the dangers of automation in terms of job losses (McKinsey & Company, 2017). Others fear even more wholesale threats to society, a dystopian future where super-intelligent robots enslave the relatively inferior humans (Barrat, 2013). Much of the AI-fear is driven by the prospects of super-intelligent AI agents (ASI – artificial superintelligence), agents so intelligent that humans will be as powerless against them as are ants against a human farmer. The literature on AI dangers focuses mostly on the unintentional dangers of AI developing into an ASI agent of destruction or danger, not because it develops a goal to kill us, but because it sees no problem in killing us in pursuit of a goal we designed it for (Bostrom, 2014).

Although fears of super-intelligent AI might be justified at some point, and although humanity needs to plan for the time and the manner in which ASI will be deployed (Bostrom, 2014), researchers have widely divergent views of when ASI agents will become reality (Walsh, 2018). Many experts are not even willing to speculate when ASI will arrive (Ford, 2018). In the meantime, a more immediate threat arises from not-yet-super-intelligent but already available AI: the ability of human attackers to use non-ASI systems to automate, enable and enhance cybercrime as we know it, as well as the ability to open totally new channels for cybercrime. Whether the long-term threat of ASI will materialize, the immediate threat of criminals using AI for cybercrime today needs to be considered – and is the focus of this article.

While focusing only on current AI capabilities, not on super-intelligent agents that are likely to emerge in the more distant future, we also focus only on intentional malicious uses of AI, not on dangers arising from unintentional consequences or on malfunction of AI systems. Neither do we discuss the threat of AI weapons, including autonomous or intelligent ones. Such systems are intended to create harm, and they can obviously be used for that purpose, whether by a legitimate authority or by a nefarious group.

Even after limiting the scope as described above, the range of capabilities of AI for achieving nefarious purposes is vast, at least as extensive if not more so than the range of capabilities for beneficial ones. Within this vast range of possibilities, we classify AI cybercrime into three general and loosely overlapping areas: using AI to commit cybercrime online, using AI via new cybercrime channels that

DOI: 10.4018/978-1-5225-9715-5.ch003

reach into physical space, and using AI or knowledge of AI to strike at the core of other AI systems, by corrupting data or algorithms. These are not three separated areas: they largely overlap, and the extent of their overlap will continue to increase. After providing a brief overview of AI history, the status of cybercrime in general, the article will delve into the three areas, highlighting the ways in which they interact presently as well as in the foreseeable future.

BACKGROUND

AI-based cybercrime is driven by two relentless forces: the development of AI, which has seen incredible strides in recent years, and the increasing volume and diversity of cybercrime, driven by more powerful technologies and more widespread use of the Internet. As background for the main topic of the article, this section will review recent trends in AI development as well as the status of cybercrime in general. The body of the article will focus on the convergence of AI and cybercrime.

Artificial Intelligence (AI)

A research field that emerged in 1956 at Dartmouth University, AI has undergone periods of excitement and growth, interspersed with periods of “AI winter” when excitement and funding dried out. The initial excitement was driven by the hope that major progress could be made swiftly in teaching computers to carry out intelligent activities. As researchers engaged with what they thought would be the most challenging tasks, the surprising discovery was that what was thought as most challenging would turn out to be easy, while some of the most effortless human skills proved most difficult to duplicate by computers. For example, computers were able to run highly complex calculations, to carry out abstract manipulations, create art (Charlesworth, 2018) and to get good at the most complex games, over time defeating the human world champions at backgammon (Berliner, 1980), chess (Weber, 1996) and most recently at Go (Hern, 2017). While the earlier successes were primarily examples of brute force computing overcoming human limited cognitive abilities, the Go victory was based on the system teaching itself to play by playing multiple games against itself (programmed with no strategy, but only with the rules of the game). To prove the point, after defeating the human champion, the Go playing AI proceeded to teach itself to play chess and defeated the chess program Stockfish 8 in a 100-game matchup (Silver, et al., 2017). Outside the field of games, AI systems are making similar progress, although at a somewhat slower pace: understanding images, natural language and achieving “common sense” turned out to be rather challenging for computers, even though such tasks were literally “child’s play” for humans.

Part of the problem with the initial failures in AI was that the approach was top-down: attempting to formalize and codify learning and knowledge, and to impart a corpus of this knowledge to the computer. This was overwhelming in terms of assembling such a corpus, as well as in terms of maintaining and debugging it. Starting in the twenty first century, the vast computing power made available by Moore’s Law, further made accessible by cloud computing and the Internet, revitalized some of the earlier attempts at using a bottom-up approach, where computers were given rules or examples and taught how to learn. Although neural networks with small numbers of neurons have been used almost from the earliest days of AI, the vast amounts of power and training data available have opened new possibilities when using much larger and deeper neural networks, an approach termed “deep learning.” While small networks are unable to improve in performance beyond a certain volume of training data, it became apparent that increasingly complex networks were able to continue to learn and to take advantage of the

huge training sets available. More than just winning at games, Deep Learning approaches using neural networks with multiple hidden layers (modeled after structures in the human brain) were successful in learning to classify videos and to use natural language (including language translation). Such systems even learned to play computer games with only receiving feedback on the outcome of the play, without being taught anything about the nature of the game (Mnih, et al., 2013). Furthermore, the ability to interact via natural language and to make some sense of context led to deployment of AI in consumer products and consumer-facing interfaces, from AI agents in smartphones (for example Apple's Siri or Microsoft's Cortana), AI-powered self-driving cars (Knight, 2017), and AI medical systems (Ng, 2016), just to give a few examples.

Among other uses more closely related to cybercrime, AI systems have been deployed in law enforcement, border control and in cybersecurity applications. For example, European Union researchers are developing a "deception detection" system to spot suspicious behavior at border crossings. Dubbed IBORDERCTRL (HomeBorderCtrl, 2018), the agent prompts users to upload travel documents and asks questions, while monitoring the traveler for suspicious behavior to provide a risk figure to the border guard for final processing. In law enforcement, VeriPol is an AI agent that can identify fake police statements using text analysis (Quijano-Sánchez, Liberatore, Camacho-Collados, & Camacho-Collados, 2018). In a real-life pilot test of the system, in only one week 64 cases of false robbery were detected and closed in two Spanish cities; for comparison, the human law enforcement agents typically detected and closed only 14 such cases on average. AI systems have also been developed to generate sketches of suspects that exceed the performance of human sketch artists (evofit, 2018). AI can even help solve previously unsolved crimes, by connecting the gunshot residue on a wound with particular types of guns or bullets in ways previously impossible to connect (Gallidabino, Barron, Weyermann, & Romolo, 2018).

Cybercrime

Traditional computer security is at increased risk today, with three quarters of the attacks motivated by financial gain (Verizon Enterprise, 2018). Cybercrime is driven by rogue nations, as well as by an organized crime industry that operates online by attacking organizations, to steal data for resale or for financial extortion (Ablon, Libicki, & Golay, 2014).

Attackers involved in cybercrime today rely mainly on rudimentary automation tools (running scripts). Attacks are carried out against known vulnerabilities, whether human or technological. For technological targets, attackers use lists of known vulnerabilities and run automated scanning tools to brute force attacks, going through the entire list of potential vulnerabilities (e.g., unpatched software or open ports). There is little intelligence in these scripts, and little if any human involvement until a vulnerability is found. Upon identifying a vulnerability, the script can execute code to take advantage of the vulnerability or can alert the human attacker to carry out additional steps.

For non-technology-related vulnerabilities, phishing and social engineering attacks focus on the weakest link in information security, the human element. Social engineering is the generic term for attacks that use psychological techniques that trick users into giving attackers access to protected resources. Using social engineering techniques involves pretending to be a person of authority or a person with a need to access information and convincing the target user to facilitate access. Alternatively, techniques involve the attacker pretending to verify the credentials of the target user (with the intention to learn these credentials and to use them later to access protected information). Phishing attacks are those where the request for credentials arrives in email form, either directing the user to submit credentials for verification on a website (or via email) or directing the target user to download or open malware. Malware

is a generic term for software that can be used as the attack vector, either by getting the target user to download it from a website or to open it as an email attachment. Malware is a pervasive problem, as attack vectors have become more powerful, more available and easier to deploy. For example, ransomware is a particularly concerning type of malware that takes over the user's data, encrypts it and requests the user to make a ransom payment to gain access to the decryption key. The threat can become even greater when combined with AI, as we detail in the body of this article.

In a perverse asymmetry, it is much easier to attack than to defend an organization. The 2018 Data Breach Investigations Report (Verizon Enterprise, 2018) finds that of the breaches reported 87% took minutes or less to complete but 68% took more than one month to discover.

Although the focus of this article is on AI-supported cybercrime from the standpoint of an attacker, AI can also be used from the perspective of defense. Many companies are utilizing AI and machine learning to detect threats and warn the user. For example, Microsoft's Defender software uses multiple algorithms and training sets to provide defense in depth in the event an algorithm is cracked. (Giles, 2018). A challenge that arises is to avoid the problem of false positives; too many will render the system unusable. While algorithms can often be tuned to minimize false positives as identified by its ROC curve, the result is a lower number of true positives. Even for this problem, AI may help find a solution. Recurrent neural networks have been demonstrated to model SQL injection attacks that learn, iterate, and adapt from false positives to reduce future errors (Wallarm, 2018).

AI-supported cybercrime has the potential to transcend all the factors that limit the scale of today's cybercrime. AI will augment, enhance and make more difficult to track the attacks.

Phishing Attacks

Phishing attacks, a type of social engineering attacks, are based on carefully researching weak spots of people and organizations, then customizing targeted attacks for these weak spots. According to an industry report, attackers created an average of 1.4 million phishing websites a month in 2017 and launched phishing attacks against 63% of the organizations surveyed for the report (Webroot, 2017).

Phishing attacks fall in two categories: mass phishing and spear phishing. Mass phishing attacks rely on sending to many users email messages, using easy to spot telltale signs: poor spelling, rather primitive formatting, relatively easy to spot fake logos and links. These telltale signs are deliberately used to elicit responses only from users with the lowest awareness of cybersecurity issues. By falling prey to such blatantly obvious lures, respondents signal that they are likely to engage with the attacker with little ability to resist, and that they are likely to provide the information the attacker is looking for. Given that most email users are at least somewhat aware of phishing threats, the telltale signs of typical phishing attacks lead to low response rates, which is acceptable and even desirable for the attacker, because the attacker lacks the capacity to engage with large numbers of respondents anyway; instead, attackers prefer to engage only with the few respondents who are most likely to fall prey to the attack. For automated phishing attacks, as described below, such considerations do not necessarily apply.

In contrast, spear phishing attacks are sophisticated and highly-targeted to carefully selected users, involving considerable prior research on the target individual, on the organization, the social networking profile and on any other relevant connections to the target user. Experts estimate that spear phishing emails are the tool of choice for 91% of the most qualified attackers (Morgan, 2017). A well-trained attacker takes only minutes to get into a target system, but this speed is based on countless hours of prior preparation and research (DeSot, 2017). This considerable time investment required on the part of the attacker clearly limits the number of victims an attacker can target; the investment of time is justified if

the target is a key gatekeeper for the information the attacker is seeking. In some cases, the respondents from the mass phishing attacks can become the targets of spear phishing attacks, or the information from a mass phishing attack can be used to identify and research other users as targets of spear phishing.

Automated Phishing Attacks

As early as 2015 experts estimated that most cyber-attacks are automated (Goodman, 2015), although attacks still require human involvement beyond a certain stage. For example, mass phishing attacks can be fully automated: the attacker designs the email message, purchases or harvests a list of email addresses for recipients, sets up a landing website where victims will be asked to verify (provide) their credentials, and sets up a database on the back end of the website, where the credentials will be stored. Phishing websites typically have a short lifetime, as they are discovered by information security professionals and blacklisted or targeted by white hat hacking counterattacks. Thus, the attacker has only a limited window to harvest credentials, but the process requires no human interaction once the site is set up. There are even tools available on hacker websites that will automate the entire process, starting with the generation of the email message, the setting up of the database and website and the collection of credentials. In contrast, spear phishing attacks are more difficult to automate. Beyond just collecting credentials, spear phishing attacks are intended to allow more comprehensive access into protected systems. After gaining access to valid user credentials, the attacker will actively use the system, for example syphoning data or installing additional tools to facilitate deeper access into the system. A recent trend is to install bitcoin mining software on breached systems, which makes it much easier to monetize a successful attack.

Cybercrime is a vast and growing field, and this introduction provides only the top-level highlights. For more information, there are many good books and papers that provide additional background. Next, the body of this article focuses on how AI is already able to enhance cybercrime.

ARTIFICIAL INTELLIGENCE-BASED CYBERCRIME

Autonomous AI agents with the initiative, motivation and the capabilities to attack humans would be the holy grail for attackers, but such agents are not likely to be developed soon. On the other hand, other simpler AI tools are already available, and they are likely being used by cybercriminals to enhance the efficiency of their attacks, to develop new attack channels or to strike at the core of data and algorithms that are used by legitimate AI. A recent report anticipates that AI will enable attacks that are “especially effective, finely targeted, difficult to attribute, and likely to exploit vulnerabilities in AI systems” (Brundage, et al., 2018). A survey of more than 1200 security executives worldwide (Thales eSecurity, 2018) found that while 64% of respondents view AI as a helper in achieving cybersecurity, 43% view the malicious uses of AI as concerning (respondents could select either or both views).

Although it is difficult to conclude when AI has been used in an attack, in an informal survey of 100 attendees of Black Hat USA 2017 62% of respondents anticipated that AI would be used for offensive purposes in the next year (The Cylance Team, 2017).

The core of this article presents examples and countermeasures for three types of cybercrime outlined in the introduction: using AI to commit cybercrime online, using AI via new channels that reach into physical space, and using AI or knowledge of AI to strike at the core of other AI systems, by corrupting data or algorithms.

Using AI to Commit Cybercrime Online

1

As mentioned before, the capabilities and the scale of attacks is currently limited by the abilities of attackers to handle either human or technological vulnerabilities. With the aid of smart AI tools, attackers will be able to identify, profile and interact with more potential victims, will gain access to attack vectors that are more credible (and more successful against their victims) and will carry out attacks that are harder to detect.

Using AI Will Enable Attackers to Use Social Engineering to Identify and Profile More Victims

Successful attacks require considerable amounts of research, in particular for spear phishing: to identify potential victims, to research the target for vulnerabilities and to design attack vectors that are most likely to succeed. Using data mining tools and techniques, attackers could use AI to automate the collection of information that could support social engineering attacks. Such uses of AI are already taking place, according to Deepak Dutt, the CEO of a mobile security startup quoted in Gizmodo (Dvorsky, 2017): AI tools are used to mine public data repositories, to monitor email messages and create personalized responses for social engineering.

Using AI Will Enable Attackers to Handle More Victims

For attacks that require human interaction, the attacker is limited in the number of victims it can handle at any given time. When using AI tools to automate the handling of user responses, many more victims can be handled at a given time. Using technologies already available, almost anybody can put together a chatbot in minutes (Ingraham, 2017); with such a tool, social engineers can then expand the capabilities of automated attacks, using the AI tool to engage the victim while posing as a human (Wasserman, 2018). Without a chatbot, if the user responds to the original email with a question or a concern rather than simply providing the credentials requested, the attacker has to engage one-on-one with the user to pursue the potential victim. When using a chatbot, the AI can handle simple inquiries and engage the user, with the hope of ultimately eliciting the credentials (Gambhir, 2017). The range of interaction for chatbots is currently rather limited, but the capabilities of AI are evolving and expanding continuously. Moreover, what such AI tools lack in sophistication they make up in volume and reach. Attacks can be launched via text (email) or voice (by phone). Ironically, a similar approach can be used to thwart phishing attackers, by getting the attackers to engage with a chatbot that will waste their time.

Using AI Will Make Attacks More Effective

Using AI can make phishing URLs more credible (Bahnsen, Torroledo, Camacho, & Villegas, 2018). Using Deep Neural Networks technologies trained on a database of more than a million phishing URLs, researchers were able to improve the efficiency of the URLs, making them less likely to be detected by defensive tools. The AI tool increased the effectiveness of two threat actors, from 0.69% to 20.9% and from 4.91% to 36.28%, respectively.

An older paper on training AI to carry out spear phishing attacks (Seymour & Tully, 2016) reported success rates of 30-66%, comparable with the 45% success rates of manual human spear phishing attacks. A journalist who tried to match forces with the AI spear phishing tool had to concede defeat: he averaged only one tweet per minute, with a response rate of 38%, while the AI agent generated six times as many tweets, with a similar response rate of 34% (Brewster, 2016).

Technologies that entice people to act are primarily developed for marketing purposes; like any tools, once developed they can be used for the intended purpose or coopted for more nefarious ones. Companies already see AI as a powerful tool to customize ads to maximize the response from potential consumers (Fati, 2016). The marketing approach uses feedback from the consumer's actions to fine-tune the marketing campaigns to further increase the effectiveness of the marketing message; using the same approach can use AI to fine-tune an attack vector to make it more effective. In the same way A/B testing is used to improve human response to marketing messages, AI can use A/B testing to increase the response rate to social engineering attacks well beyond improving the efficiency of phishing URLs. Ultimately, both the marketing campaign and the phishing campaign exploit the same human weaknesses and heuristics.

Another way AI can enhance the effectiveness of phishing is by allowing attackers to better impersonate others. Without AI, attackers build a credible persona, posing as a helpless customer or a vendor in need of special access on a short notice, but have a difficult time impersonating somebody known to the target. They can try to impersonate via email (spoofing the sender address) or via another channel where they are not easily recognized (faking somebody's voice on the phone). On the other hand, AI techniques already enable attackers to impersonate specific individuals, some who might be well-known by the victim, using much more impactful video or audio channels.

Deep learning techniques have been shown to deliver realistic computer-based impersonation through audio and video. Using samples of audio or video from a human target A and a video of another human B, machine learning is able to extract the key features of the target A and synthetically alter the audio and video of B to generate a realistic-looking video of A (dubbed a "deepfake"). Such audio and video deepfakes have already been the subject of "fake news" in which politicians appear to be making statements they did not actually make (Feathers, 2018), or celebrities appearing to act in pornographic videos (Bloomberg, 2018). While many concerns have been voiced about using deepfake videos for political or blackmail purposes (Chesney & Citron, 2019), the same technique can be used to create a Skype video of the victim's boss or to imitate the boss's voice in a voicemail. Standard procedures involve close screening of unexpected visitors on company premises, but most employees in any organization would gladly accommodate the visitors upon receiving a Skype or telephone call from someone who looks and sounds like their boss.

So far, AI tools that create deepfake videos are still expensive, which limits their use. The actual rendering of the person impersonated is convincing, yet not foolproof. Videos that have convinced many online viewers can be identified as fake only by experts, for example by evaluating the blinking behavior (Li, Chang, & Lyu, 2018). On the other hand, as AI tools get better at using natural blinking, detecting such fake videos will become increasingly more difficult even for experts.

One final way to make attacks more effective is to use AI to make intelligent scanners for technological vulnerabilities. We described earlier how attackers use brute force to test systems against lists of known vulnerabilities. Using AI, attackers will be able to program the AI to test for new vulnerabilities, for example using techniques from genetic programming.

Using AI Will Make Malware More Difficult to Detect

Today, malware attempts to obfuscate itself and may undergo mutations to hide itself from detection by virus scanners. AI-based malware has the potential to conceal itself in an intelligent manner, making it almost impossible to detect until its payload has been triggered. An IBM prototype, DeepLocker, has been developed to demonstrate this type of attack by hiding ransomware until activated by the face of a specific person (Stoecklin, 2018). Moreover, finding exploits to break into a system can also be enhanced by AI. In 2016, Carnegie Mellon's Mayhem AI won the DARPA Cyber Grand Challenge which involved automated scanning and attacking of adversary systems. Not surprisingly, the best defense against attack AI systems is to use defensive AI that can automatically detect, self-patch, and recover from attacks (Avgerinos, 2018).

Another example of AI helping make attacks more difficult to detect is in money laundering. Money laundering online can involve something as simple as multiple transfers of funds among many bank accounts, shuffling the money and making its source difficult to retrace. When using AI to control such schemes, it is possible to scale the shuffling until it becomes truly impossible to unwind. An actual case involved 250 accounts with money transferred among them (Patterson, 2018). It is already possible to manually set up a network of such transfers, but, using AI, the attacker can dynamically change the pattern of transfers, as well as learn from experience.

Using AI via New Cybercrime Channels that Reach Into Physical Space

Another class of cybercrime enabled by AI tools is to use the tool as a channel for new types of attacks. Any new technology creates new crime channels, maybe not surprising in retrospect, but surprising the first time. For example, a casino was breached via an Internet-connected thermostat in its gigantic fish tank (Clifford, 2018). Although not a case of AI-mediated cybercrime, this is an example of a crime channel that did not exist before the advent of the Internet of Things. AI will enable other surprising types of attacks that will only be considered when the technology to enable them will become available.

There are already reports of attackers using voice commands to get devices to unlock front doors of homes (Tilley, 2017). Similarly, personal assistant agents can be accessed via voice by an attacker on computers that are locked, for example to install malicious software (Kovacs, 2018). Since voice interaction devices are designed primarily for convenience, they are similar to the ideal victims of social engineering: primed to serve and accommodate, rather than question and protect. Current generations of voice interaction devices are not designed to recognize individual voices, but only to recognize and execute commands. As such, an attacker may ask a device to unlock the front door of a home they are breaking into, or may place an order for expensive merchandise with the intention of stealing it once it is delivered on the doorstep. Some attacks can even be targeted to a voice interaction device, but cannot be heard by nearby humans (Smith, 2018). An audio stream that appears innocuous to a human listener could in fact instruct the device to place an order or to execute a malicious action. This type of attack is part of the more general attacks on AI algorithms we describe in the next section. Until vendors will offer systems designed with security in mind, the designs focused only on convenience leave massive vulnerabilities in place.

Another type of attack channel is to use AI to generate counterintuitive artifacts in the physical world. For example, researchers have shown that it is possible to produce synthetic fingerprint templates that would match multiple users in a database (Bontrager, Roy, Togelius, Memon, & Ross, 2018). In general,

such attacks involve reverse engineering the AI recognition function. Attack AI systems called Generative Adversarial Networks (GANs) involve two systems, one that generates patterns and one that discriminates (evaluates) patterns, providing feedback on a measure of goodness of the patterns. The generator starts initially with random noise, then modifies the design via feedback from the discriminator system. Over time, using the feedback from the discriminator system, the generator can converge to producing patterns that are recognized as “good” by the discriminator. Both systems are programmed to co-evolve, making sure that as the generator improves in its ability to create more realistic patterns the discriminator becomes stricter in its evaluation process. In the earlier example, researchers used GANs to synthetically generate DeepMasterPrints, fingerprint patterns that can match a large number of user fingerprints in a database. Without attempting to match a particular user’s fingerprints, the system attempts to create fingerprint templates that look realistic and that match many users. Such DeepMasterPrints were shown to match 23% of users in a dataset at false match rate of 0.1% and a whopping 77% of users when the false match rate was 1% (Bontrager, Roy, Togelius, Memon, & Ross, 2018). For the actual attack using the synthetic pattern, a fingerprint replica could be created and used to gain access to a device with a fingerprint reader, with no knowledge of the actual fingerprint that is intended to unlock the device, the equivalent of a biometric master key.

Yet another type of physical attack using AI is to program or reprogram autonomous devices for malicious purposes. Such autonomous devices could include self-driving cars, for example to harm a given passenger or to harm a target pedestrian encountered during a trip. Autonomous drones owned by the attacker could be programmed and loaded with explosives, targeting a particular victim, or they could be hijacked from the fleet of a delivery organization and used for similar purposes. In 2016 a security researcher demonstrated how a professional drone could be hijacked remotely by exploiting the lack of encryption between the drone and controller (Rodday, 2016). Finally, robots, either in a household or in an industrial setting, can be used for corporate sabotage (Brundage, et al., 2018). Cleaning robots make up a majority of the number of robots worldwide, and they could be loaded with explosives or otherwise rigged to attack a human target.

Using AI or Knowledge of AI to Strike at the Core of Other AI Systems

The third type of cybercrime described in this article targets data and algorithms. The fingerprint attack discussed earlier is an example of using AI to attack at the algorithm level. An attack at the data level could involve stealing user data internal to the AI. For example, voice interactive devices that listen for commands can also record sounds, save them and possibly send them to third parties. In one case, a recording of a husband and wife conversation was sent (apparently thanks to a bug in the AI) to a person on their contact list (Zhou, 2018). More deliberately, an attacker could set the device to record such conversations, to be retrieved later and mined for data.

More attacks have been reported on the algorithm side than for data. For example, an image recognition system could be presented with an image crafted to look like a panda to a human observer, but to be recognized by AI as a car (Polyakov, 2018). The introduction of objects that were not encountered together in the AI training set can have strange and devastating effects on the accuracy of image recognition, with global and shift-variant effects (Rosenfeld, Zemel, & Tsotsos, 2018). For example, introducing an object in an area of the image affects the recognition of objects far away from the introduced object. Proximity of objects not typically found together can result in shift-dependent artifacts (an image featuring only a keyboard and a hot dog can be recognized as a dog, a teddy bear or a person in different areas of the

image, depending on the relative location of the two objects). In another adversarial attack, images showing widely different scenes (school bus, dog, pagoda, nature scenes) are modified only slightly, but the visually indistinguishable new images are all recognized as showing an ostrich (Szegedy, et al., 2014). In another paper, researchers added a noise background to a panda image that was initially recognized as such by the AI with 53% confidence. The modified image is indistinguishable from the original for the human observers, yet AI recognized it with much higher (99.3%) confidence, this time as a gibbon (Goodfellow, Shlens, & Szegedy, 2015). Finally, images that make no sense to human observers can be designed to be recognized with high confidence by deep learning systems (Nguyen, Yosinski, & Clune, 2015). Whether such image recognition systems are used for security (face recognition) or for another type of application, attacks on the algorithm can allow criminals to hijack the system by injecting noise, adding unexpected objects in the image frame or adding special markers to change the recognition process.

For face recognition applications, AI has been shown to enable attacks, using face markings or image transformations that would be classified correctly by human observers, but that would confuse deep learning algorithms. At the same time, AI tools are starting to identify such modified images, with the goal to increase the robustness of the recognition (Goswami, Ratha, Agarwal, Singh, & Vatsa, 2018). A similar technique might be applicable to the other attack vectors described in this section.

Modifying objects in the physical world (using stickers or markings) can also lead to faulty recognition, for example applying tape markings to a Stop sign can lead to it being recognized as a Speed Limit 45 mph sign (Eykholt, et al., 2018). Such attacks could induce a self-driving car to crash into oncoming traffic, as it speeds past the stop sign, rather than giving right of way. Attacks on speech-to-text translation systems can take any given sound clip (speech or non-speech) and optimize it into an adversarial input that is 99.9% similar to the original sound clip, but that is recognized as any given (different) target phrase. This is similar to what we described for attacks on the voice-interaction devices in the previous section. For example, an AI-crafted phrase that sounds to a human “without the dataset the article is useless” is recognized by speech recognition AI as “okay Google browse to evil dot com” and a brief AI noise-enhanced clip from Bach’s Cello Suite #1 (no speech) is recognized by speech recognition AI as “speech can be embedded in music” (Carlini & Wagner, 2018).

Adversarial attacks on reading comprehension systems have been shown to greatly reduce the accuracy of the AI, from an average of 75% to less than half (Jia & Liang, 2017). When attackers used grammatically incorrect words, the accuracy plummeted to 7%. Such attacks, whether using video, text or some other type of media, could hijack an algorithm to make it serve the purposes of the attackers, instead of its original functionality. In all the results discussed above, the adversarial input is optimized to create maximum error in the recognition system with minimum change in the input to the system. Such approaches are so called “white box,” because they require access to the recognition system, with intimate knowledge of how it is built and trained, as well as time to train and optimize the attack. This set of conditions might be available to attackers when systems use algorithms that are open source, widely available online.

FUTURE RESEARCH DIRECTIONS

As happened in the early history of the Internet, which was designed for a small group of technically savvy people who trusted each other, AI tools are currently designed for convenience and flexibility. Security is an afterthought if at all a consideration, and vendors focus on only two goals: convenience for the user and flexibility in accepting voice variations with age, health or different accents. Given how

difficult it is to retrofit security on the open architecture of the Internet, designers of AI tools should take heed and incorporate cybersecurity considerations early on. Additionally, “transparent AI” that allow the user to see how AI linked an input to an output will help debug some of the algorithm attacks on AI.

An interesting wrinkle will arise in correcting the behavior of AI, when needed. Some researchers advocate that when ASI agents become conscious they will gain rights like conscious humans: this will raise ethical issues about “turning off” or even “reprogramming” a conscious ASI (Bostrom, 2014). Some researchers even go as far as advocating for a mental health approach to “treating” misbehaving AI (Behzadan, Munir, & Yampolskiy, 2018). Other researchers are advocating a governmental agency to coordinate and eventually regulate AI, attracting AI practitioners to civil service, identifying relevant policy issues and even paving the way to international AI governance (Clough, 2018). Even when fighting an adversarial AI system, the question will remain on how to defeat it humanely if it is conscious.

AI learning is not robust to changes. For example, an AI system was able to learn to play one of the early computer games, Breakout, quite well, but the performance plummeted even for a small change that offset the paddle by a few pixels (Kansky, et al., 2017). As such, AI could be trained efficiently to attack a specific target, but would be difficult to train against a variety of attackers. On the other hand, such weaknesses in AI could be used to defend against AI-backed attacks, by slightly changing the landscape where the attack takes place.

CONCLUSION

There are strong voices urging humanity to plan for when super intelligent AI might turn against us. In the meantime, a more urgent need is to understand and respond to dangers from not-yet-super-intelligent AI that is used as a tool by malicious attackers. As Pedro Domingos feared, “[p]eople worry that computers will get too smart and take over the world, but the real problem is that they’re too stupid and they’ve already taken over the world” (Domingos, 2018). Given the financial payoff of cybercrime, the scale on which both rogue states and organized crime use cybercrime, it is a matter of time until AI becomes a tool of choice supporting criminal activities. Although this article describes the state of the art, technology evolves very fast, and attacks vectors will change from what is described in this article. It is nonetheless imperative for security professionals to be aware of the role of AI in cybercrime, of ways to defend against it, and of ways in which it will change their profession.

INTRODUCTION

Following the surge in false stories during the 2016 U.S. elections, there has been increased scrutiny on the phenomenon of fake news by practitioners, academics, and policymakers (Allcott & Gentzkow, 2017; Silverman, 2016). Fake news has gained prominence throughout the world since then, with the intent or potential to undermine public institutions, incite social tensions, and interfere with political processes in affected countries (Select Committee on Deliberate Online Falsehoods, 2018; Tan & Ang, 2017). Consequently, governments worldwide have been deliberating and stepping up on legislative and non-legislative measures to combat the threat of fake news to social and political stability (Hacıyakupoglu, Hui, Suguna, Leong, & Abdul Rahman, 2018). Furthermore, mounting pressure on technology companies to manage the spread of fake news has led tech giants such as Google, Facebook, and Twitter to pioneer efforts to address this problem (Drozdiak, 2018; Foo, 2018).

However, the study and management of fake news is a complex issue. To begin with, the concept of “fake news” is not new as the origins of fake news can be traced back to ancient Rome, where it has been used as a method to consolidate political power. Most famously, during a power struggle for the Roman Empire in 32 BC between Octavian and Mark Anthony, Octavian illegally ‘acquired’ and read out Anthony’s will to the Roman Senate as proof that Mark Anthony had betrayed the Roman people and that he was a puppet of the Egyptian queen Cleopatra (Johnson, 1978). To this date, the degree to which Octavian tampered the contents of the will before he read it out to the Senate, is still debatable (Sirianni, 1984). Nevertheless, history will show that it succeeded in turning the people of Rome against Mark Anthony (MacDonald, 2017). This is just one of many cases where fake news has influenced the way people live their lives.

DOI: 10.4018/978-1-5225-9715-5.ch004

Recognising its potential impact on society and national security, this phenomenon has become an important topic to examine and understand. Existing studies on fake news has focused on different areas of research, such as identifying the actors behind the creation and spread of fake news (Marwick & Lewis, 2017), as well as the psychological vulnerabilities of individuals which contribute to their beliefs in false information (Ecker, Lewandowsky, Fenton, & Martin, 2014).

Another emerging area of concern is the connection between fake news and crime. From the ‘Pizzagate conspiracy’ in the United States which led a man to fire his rifle in a restaurant after conspiracy theorists linked it to a fictitious child sex ring (“‘Pizzagate’ gunman sentenced to four years,” 2017), to false rumours instigating violence and destruction of Muslim properties by Buddhist mobs in Sri Lanka (Taub & Fisher, 2018), fake news has become intertwined with criminal offences of various magnitudes across the globe. Singapore, for example, has also seen a recent emergence of bitcoin investment scams that employ fake news to deceive their victims (Tee, 2018). Despite this emerging nexus between fake news and criminal conduct, there is a dearth of literature examining this convergence to date.

Understanding Crime-Fake News

For the purposes of this chapter, fake news is defined as content that contains inaccurate, misleading, or fabricated information about current events, which is distributed through different channels of communication such as print, broadcast, text messaging, or social media (Chen, Tan, Goh, Ong, & Khader, 2018). Such false content can become implicated with a crime if they are adopted for criminal purposes that result in harm to an individual or society. For example, individuals with malicious intent may spread fake news about a specific group of people being involved in criminal activities in order to incite communal outrage and violence against them (Phartiyal, Patnaik, & Ingram, 2018).

To better examine this association between fake news and crime, the purview of the criminal law needs to be considered. The criminal law, as established and imposed by a state or country, determines which acts constitute a crime and the corresponding punishment associated with them, such as fines or imprisonment, to deter engagement in such acts (Jung, Ahn-Redding, & Allison, 2014). Regarding specific legislation that targets fake news content or people who spread them, only a few countries have implemented and maintained such laws at the time of writing. Under Malaysia’s Anti-Fake News Act, individuals who deliberately spread fake news can be fined or imprisoned, while Germany’s Network Enforcement Act targets the removal of fake news content that is dangerous to public discourse and public peace (Jayakumar, 2018; Venkiteswaran, 2018). Other countries like South Korea and Singapore are mulling over the creation of new laws to combat fake news (Kim, 2018; Sim, 2018).

However, there are existing provisions within the law that can be used to prosecute parties that spread online falsehoods. Within the current Singapore¹ legislative framework, Goh (2018) and Mok (2018) have identified six of such offences that can warrant criminal charges: sending false messages, promoting enmity between races or religions, criminal defamation, sedition, causing public alarm, and spreading fake terrorist threats. Furthermore, there are two more offences of note that are relevant to Singapore. The first is contempt of court which may involve making and spreading false claims that scandalise or undermine the judiciary, while the second concerns unauthorised access to digital data through scams that may employ fake news to lure victims to disclose their personal information (Tee, 2018; “What is the Offence of Contempt of Court?,” 2018). Following the recent recommendation by the Select Committee on Deliberate Online Falsehoods for the Government to “consider supporting or conducting research to understand society’s vulnerabilities” (Select Committee on Deliberate Online Falsehoods, 2018, para. 309) to deliberate online falsehoods, there is a need to widen the evidence base to increase our understanding about this phenomenon.

Thus, an exploratory study on fake news cases (from 2013 to 2018) in Singapore has been conducted. These are crime-fake news cases which have come into contact with the criminal justice system in Singapore. This study also aims to provide an exploratory outlook on the following: (a) the type of crime-fake news in Singapore, (b) the impact that crime-related fake news (or crime-fake news) has on the victims as well as society, (c) the profile of the fake news creators and their motivations, (d) the channels of transmission, as well as (e) the response to mitigate the crime-fake news.

EXPLORATORY STUDY ON FAKE NEWS AND CRIME IN SINGAPORE

Methodology

Data Collection

Online English-language newspaper articles were identified on Google News using the following keywords: ‘Singapore’, ‘false’, ‘misleading’, ‘allegations’, and ‘rumours’, from 1 January 2013 to 1 October 2018. A total of 21,293 online articles were collected.

The start of the data collection was fixed at 2013 as it coincided with the start of the S.U.R.E² campaign. This is Singapore’s first campaign on information literacy awareness, which was launched to improve the general public’s online information literacy and information-seeking habits (Tan, Wan, & Teo, 2014).

32 cases of fake news incidents were subsequently sieved out based on four inclusion criteria. Firstly, in line with the definition of fake news, the case must contain an inaccurate, misleading or fabricated content about current events.

Secondly, it must be an incident that involved Singapore in one of the following ways: (a) an incident that took place in Singapore, (b) an incident where Singapore was directly implicated even if it occurred outside the country, or (c) members of Singapore’s community were involved.

Thirdly, the case must have a criminal element and be serious enough to be implicated with the criminal justice system – whether with the law enforcement agency or the judiciary. As such actions ranging from police reports to court cases are grounds for inclusion.

Lastly, in the event where multiple articles regarding the same fake news incident are present, these articles were counted as a single fake news case.

Coding and Analysis

A content analysis methodology was utilised to analyse the cases. Two independent coders coded the 32 cases along the following domains: type of crime-fake news, impact on Singapore, the identity and motivations of the fake news creator, affected parties, the channel for transmitting fake news, responders to the fake news, and actions taken in response to the fake news. The categories within each domain were developed from a ground-up approach using open, axial, and selective coding (Strauss, 1987). In cases where a consensus on a code could not be achieved, it was resolved via discussions amongst the two coders. For the reliability analysis, Krippendorff’s alpha (α) was run and the values were acceptable (all values where $\alpha > .800$, except for 1 variable where $\alpha = .750$).

ANALYSIS AND DISCUSSION

The Different Types of Crime-Fake News

In order to explore the manifestation of crime-fake news, information on the crime element present in each case was recorded. As a result, seven categories have emerged (see Table 1). The top four most prevalent categories are defamation (e.g., newspaper articles alleging wrongdoing by the local football association), public alarm (e.g., a kidnapping hoax), financial (e.g., a bitcoin investment scam), and false information (e.g., false information which claimed that the local government cancelled *halal* licenses for a large number of eateries).

Table 1 illustrates the three overarching types of crime-fake news. Firstly, there are 6 cases of fake news-assisted crime (18.75%). Within this category, the crime-fake news comprises fraudulent schemes of a financial nature such as get-rich-quick scams (2 cases), phishing scams (3 cases) and one case of an impersonation scam where the scammer impersonated a local politician and began asking for money.

Secondly, there are 8 cases of fake news which harms public order. Fake news under this category are more closely associated with hoaxes (21.88%). This is expected as hoaxes tend to fuel public alarm (e.g., hoaxes inciting fear in parents over stories about child kidnapping in public spaces), which may lead to public unrest amongst those affected by it.

Finally, for fake news-centric crime, there are 18 cases (56.25%). There is a wide range of criminal elements identified amongst the cases, half of which contains defamation (31.25%). This suggests that most crime-fake news incidents are perpetuated to spread false statements online in order to harm the reputation of others.

Table 1. Crime-fake news identified

Crime-fake news	Crime categories	Description	Counts	%
Fake news-centric crime	Defamation	Publishing falsehood intended to defame or harm a person or an entity's reputation.	10	31.25%
	False information	Knowingly spreading false information online that can lead to serious consequences.	4	12.50%
	Contempt of court	Publishing false allegations that scandalises the integrity or impartiality of the judiciary or undermine public confidence in the administration of justice.	2	6.25%
	Sedition	Covers conduct or speech that raises discontent or disaffection among residents of Singapore, brings into hatred or contempt or create dissatisfaction against the government, or promotes ill-will or hostility between different races or classes in Singapore.	2	6.25%
Fake news which harms public order	Public alarm	Knowingly spreading falsehoods that are likely to cause widespread fear and alarm among the public.	7	21.88%
	False terror threat	Spreading false information that causes others to believe that a terrorist act will be carried out.	1	3.13%
Fake news-assisted crime	Financial	Covers fraudulent and dishonest schemes that acquire money, information, or other personal property from unsuspecting individuals.	6	18.75%

The Impact of Crime-Related Fake News on National Security and Social Cohesion

Information regarding the impact of the fake news incident on society was recorded for each incident. As a result, three main categories emerged (see Table 2): (a) fake news which had an impact on national security, (b) fake news which affected social cohesion, and (c) others.

Nine cases (28.13%) had some degree of impact on Singapore's national security. Within this category, it can be further demarcated into three subcategories. For fake news that impacted law enforcement, it revolves around cases which are serious enough to necessitate a response by the authorities. These can be hoaxes which threaten public order (e.g., hoax criminal activities or hoax kidnapping claims), or false accusations about the conduct of law enforcement officers (e.g., a misleading story about a potential police crackdown on a protest). For those associated with terrorism, it refers to terror hoaxes or allegations about an individual being linked to a terror group. Lastly, there are instances where the crime-fake news touch on issues relating to both law enforcement and terrorism.

For social cohesion issues (12.50%), two subcategories were identified: issues affecting race and religion tension (e.g., false claims that Eurasians in Singapore were considered as Indians under Singapore law) as well as xenophobia sentiments (e.g., false claims that foreigners disrupted a religious procession) in Singapore.

Nineteen cases are concerned about other issues (59.38%). These are issues that did not pose a threat to national security and social cohesion. The prevalent subcategories in this category revolved around fraudulent activity (associated with scams), food safety, and contempt of court.

Table 2. Impact in Singapore society

Categories	Subcategories	Counts	%
National Security	Law enforcement	6	18.75%
	Law enforcement + terrorism	2	6.25%
	Terrorism	1	3.13%
Social Cohesion	Xenophobia sentiments	2	6.25%
	Race and Religion issues	2	6.25%
Other Issues	Fraudulent activity	4	12.50%
	Food Safety	3	9.38%
	Contempt of Court	3	9.38%
	Government Actions	2	6.25%
	Environment	2	6.25%
	Defamation	2	6.25%
	Water Contamination	1	3.13%
	Misidentification	1	3.13%
	Deceptive Advertising	1	3.13%

Fake News Creators

Identity of Creators

Several key observations were made during the process of identifying the creators of these crime-fake news. Firstly, in a large proportion of the cases (17 cases; 53.13%), the identities of the fake news creators were difficult to determine due to lack of identifiable information. For example, the identity of the perpetrator could not be established as the perpetrator was using an online alias or that the fake news message was completely anonymous. Secondly, even among those cases where the fake news creators were identified, there were a handful of repeat offenders (which are alternative media outlets in Singapore): The Real Singapore (two cases), The Online Citizen (two cases), All Singapore Stuff (two cases). For the remaining nine cases (28.13%), the identified perpetrator was involved only in one case, and there was no distinct purveyor amongst them.

Motivations

Information on the motivations for the fake news creators was inferred based on (a) the content of the crime-fake news that was transmitted, and (b) if the motivation was reported in the newspaper articles. Table 3 showed the breakdown of the motivations of the fake news creators. Besides a broad range of motivations driving fake news creators, some of them are motivated by more than one motivation. For eight of the cases, there was more than one motivation coded; three motivations coded in two cases, two motivations coded in six cases.

The top four motivations were to influence political outcomes (e.g., claims that a racial minority population was being suppressed by the government), gain profit (e.g., scams), advance social issues (e.g., claiming that the judges were biased against LGBT issues in Singapore), and cause material or reputation harm (e.g., claims that a local business was selling contaminated food with intention to harm the business' reputation). These findings largely corroborated the existing literature on fake news, which identified the endeavour to influence politics and create profit as the main drivers for fake news creators (Chen, 2018; Soon & Goh, 2017; Wardle, 2017). There were also 10 cases in which the motivation was unclear; they were all hoaxes, which are content created by unknown sources with the intent to deceive.

Table 3. Motivations of fake news creators

Categories	Coding description	Counts	%
Politics	Crime-fake news is targeted towards politicians, political parties, or fanning anti-establishment sentiment	11	26.19%
Profit	For the purpose of monetary gain	9	21.43%
Social Issues	To advance an issue that society is concerned about	5	11.90%
Reputational or material harm	Intention has been established to carry out reputational or material harm against an individual or a group	5	11.90%
Seeking Attention/Status	For entertainment value, personal curiosity, personal enjoyment and as a way of gaining status and acceptance within online communities.	1	2.38%
Mistakes	Factual errors made during the process of publication of information for which there has been an apology made or a correction	1	2.38%
Unclear	If the above motivations are not found or no clear indications are present	10	23.81%
Note: more than one motivation may be coded per case as more than one motivation can be present			

Channels of Transmission

Channels of transmitting crime-fake news were inferred by identifying the channel where the message originated from (see Table 4). Crime-fake news had predominantly spread via social media channel (12 cases), with Facebook (8 cases) being the most widely used mode of transmission. This finding is not surprising since Facebook is the most active social media platform in Singapore (We Are Social Singapore, 2017), ensuring that the crime-fake news can achieve a wider outreach.

Another common channel is the local citizen journalism sites (e.g., All Singapore Stuff, STOMP, The Online Citizen etc.), which were seen in 8 cases. One explanation for the prevalence of this category is that these channels would accept and circulate posts from any online contributors. As a result, these posts were often not checked for the veracity of their claims, which makes the channels more susceptible to be exploited by crime-fake news creators.

Response to Mitigate the Crime-Fake News

Information on the actions taken to mitigate the crime-fake news was recorded. In 53.13% of the cases (17 cases), the local authorities were involved in responding to it (see Table 5). Under the category of ‘government’, the Singapore Police Force (6 cases) and the Attorney-General’s Chambers (4 cases) are the most frequent responders to cases of crime-fake news. The Singapore Police Force were mainly responding to cases of public alarm and/or allegations against the police, while the Attorney-General’s Chambers was responding to cases involving contempt of court, the spreading of false information, and sedition.

Concerning the actions taken against the crime-fake news, filing a police report is an action that is commonly employed by affected individuals (77.78%) and private sector/NGO (66.67%). Although there was a sizeable number of private sector/NGO (non-governmental organisation) who responded to fake news, only one of them responded twice (i.e., National Trades Union Congress FairPrice Co-Operative). Nine affected individuals responded to the crime-fake news incident but none of them responded more than once.

Table 4. Channels of transmission

Categories		Counts	(%)
Social Media	(Facebook)	8	24.24%
	(Social Media [Unspecified])	4	12.12%
Citizen journalism sites		8	24.24%
Messaging platform		4	12.12%
Blog		2	6.06%
Website		2	6.06%
Fake website		2	6.06%
Foreign Media		1	3.03%
Offline	(Notes pasted in public spaces)	1	3.03%
Unspecified reports		1	3.03%
Note: more than one channel may be coded per case as more than one channel can be used to spread crime-fake news			

Table 5. Response to fake news in Singapore by responders and action

Responders	Actions taken	Count	(%)
Government	Police statement	7	21.88%
	Police Report	4	12.50%
	Arrest	2	6.25%
	Charged in court	2	6.25%
	Court Order under POHA	2	6.25%
Affected Individual	Police Report	7	21.88%
	Charged in court	2	6.25%
Private Sector/NGO	Police Report	4	12.50%
	Police statement	1	3.13%
	Charged in court	1	3.13%
Notes: An explanation for actions taken categories are as follows: Police Statement: Cases whereby the police issued a formal statement to address the issue due to its potential impact on the public. Police Report: Cases whereby a police report was filed by a victim concerning the false information, warranting further police investigation. Arrest: Cases whereby a police arrest was made due to the offence, but without information on whether the perpetrator was charged in court. Charged in Court: Cases whereby the perpetrator was identified and charged in court for having committed an offence. Court Order (Protection of Harassment Act): Cases whereby a court order addressing the removal of the fake news was issued under the Protection of Harassment Act. In the Singapore legislative framework, Section 15 of the Protection from Harassment Act is a judicial remedy that can be applied to remove statements containing falsehood (Goh, 2018).			

SOLUTIONS AND RECOMMENDATIONS

Accounting for Differences in Fake News Creators

The exploratory study identified seven motivations for creating crime-fake news. As a result, responses against these fake news creators should take into consideration the differences in their motivations, to ensure that appropriate interventions can be identified and implemented. This is important as excessive interventions introduced to mitigate the crime-fake news may create unwanted backlash for the government. This is especially so, when these actions are construed as acts of censorship or state propaganda. In contrast, inaction or inappropriate responses to crime-fake news may inadvertently result in further proliferation of fake news (Pennycook, Cannon, & Rand, 2017).

Engaging with Multiple Stakeholders to Combat Fake News

It might be tempting to think that it is the responsibility of the government to respond to fake news in general, as they have prior experience in responding to such incidents, and that they have more resources at their disposal to do so. However, given the accelerated rate at which information is created and disseminated online, it is not feasible for the authorities to monitor and respond to all incidents of crime-fake news. Therefore, there is a need for authorities to engage with multiple stakeholders to combat crime-fake news.

Working With Social Media Companies to Curb the Spread of Fake News

As seen in Table 4, the most prevalent channel for transmitting crime-fake news is through Facebook, which highlights the need for social media companies to be involved in combating fake news. While social media companies are not direct creators of fake news, the abuse of their platforms and online services to propagate fake news places a responsibility on these companies to play a role in keeping the global information ecosystem safe from malevolent actors. As the Select Committee on Deliberate Online Falsehoods noted, “Technology companies have a social responsibility to contribute to a clean Internet information ecosystem” (Select Committee on Deliberate Online Falsehoods, 2018, para. 463).

Authorities can work with social media companies to develop reporting resources to enable the online community to self-police the platforms where the spread of crime-fake news occurs. From a crime prevention perspective, the development of such resources can increase the operating risk of spreading crime-fake news on these platforms for potential offenders (Holt & Bossler, 2016), as the online community is empowered to report those who peddle fake news with criminal intent.

Additionally, social media companies are best placed to combat fake news as they have the capabilities to take down, monitor, and detect the spread of fake news on their platforms (Weedon, Nuland, & Stamos, 2017). Thus, these companies can work in tandem with law enforcement to shut down crime-fake news and take action against the offenders.

Building a Media-Literate Citizenry

It is important to build a media-literate citizenry who can exercise scepticism and critical thinking as they consume information online. In Singapore, the National Library Board of Singapore launched a S.U.R.E campaign to increase information literacy in the public by encouraging individuals to perform four steps when handling information: (1) check whether the information source is reliable, (2) understand the context of the information, (3) research into other sources to verify the accuracy of information (cross-check), (4) evaluate the best way to use the information (Tan et al., 2014). In addition, skills such as fact-checking and understanding the effect of cognitive biases (Soon & Goh, 2017) can prepare the public to combat fake news in general.

Another avenue to enhance media literacy and deter potential perpetrators is to inform users on what behaviours are acceptable and unacceptable in online communities. This ensures that they apprehend the implications and consequences of creating and spreading fake news online. Such measures can be implemented through ‘Internet Use Policies’ that informs users of the rules that they have to abide by, such as the prohibition of inflammatory or discriminatory statements (Holt & Bossler, 2016). If any user ends up posting and spreading fake news within these sites despite agreeing to them, then they would not be able to use the excuse that they did so out of ignorance or without ill-intent.

FUTURE DIRECTIONS

This current study is an exploratory research on the emergence of a crime-fake news nexus in Singapore. It is important to recognise the limitations associated with the study. For example, it is possible that certain crime-fake news incidents were missed because it was not prominent enough, and/or that the fake

news was reported through non-English language articles (which were not picked up during the search process). Thus, future research should examine crime-fake news that are propagated in other languages such as Mandarin, Malay, or Tamil. This may widen the evidence base for informing the creation and implementation of policies to contain the spread of crime-fake news.

CONCLUSION

Fake news can exert a profound impact on society, especially when they are also associated with criminal activities. The present exploratory study into the nexus between fake news and crime paints a complex picture of this phenomenon. It attempts to highlight the various types of crime-fake news, the impact it can have on the society, the different motivations driving each case, the channels used to transmit fake news, and the different responses taken to mitigate each fake news case. By identifying contours in this nexus of fake news and crime, this study hopes to contribute to and guide future research in this area.

KEY TERMS AND DEFINITIONS

Alternative Media Outlets: In Singapore, this refers to platforms which are not under the ownership of Singapore’s mainstream media organisations: Mediacorp and Singapore Press Holdings. These sites predominantly accept posts from contributors who may be anonymous.

Axial Coding: The process of identifying the relationships between the categories and linking them together. The process yields subcategories that are grouped under a specific category. This process takes place after open coding.

Crime-Fake News: Fake news content which commits a transgression within the legal system in Singapore that can warrant a fine, imprisonment, or both.

Fake News: Content that contains inaccurate, misleading, or fabricated information about current events, which is being distributed through different channels of communication such as print, broadcast, text messaging, or social media.

Open Coding: The process of repeating readings of media sources and a line-by-line analysis of the data in order to open up the data to understand the meanings and concepts in it. Open coding includes the labelling of concepts and creating categories for comparison.

Select Committee on Deliberate Online Falsehoods: In 2018, a Select Committee on Deliberate Online Falsehoods was set up by Singapore’s parliament to examine and report on the phenomenon of the use of digital technology to spread falsehoods online. They have since unveiled 22 recommendations to combat online falsehoods.

Selective Coding: The process of further linking the categories from axial coding into a core category. This process takes place after axial coding.

ENDNOTES

- ¹ The discussion on the laws are presented here only for discussion purposes. As there are always amendments to the law over the years and new Bills being passed in Parliament. Information is up to date as of Dec 2018. This is because Singapore passed a law in April concerning fake news, which means that information is not updated at this stage.
- ² The National Library Board branded the information literacy campaign as S.U.R.E., which stands for Source, Understand, Research and Evaluate. It encourages people to do 4 steps when handling information: (1) check whether the information source is reliable, (2) understand the context of the information, (3) research into other sources to verify the accuracy of information (cross-check), (4) evaluate the best way to use the information.

Unveiling Cybercrime in a Developing Country

INTRODUCTION

Information and communication technology (ICT) networks, devices and services are increasingly critical for day-to-day activities (ITU, 2015). These ICTs arguably have therefore become necessary elements in our everyday lives and businesses for the past few decades (Bankole & Bankole, 2017). Despite the enormous benefits of ICTs, there exist a myriad of malicious use of these technologies which translate into financial loss to individuals, organizations and States. Unmistakably, cybercrime poses the biggest threat to the digital society (van de Weijer & Leukfeldt, 2017). Whereas the cost of cybercrime in 2015 was valued at \$3 trillion (Cybersecurity Ventures, 2017), Forbes (2017) conjecture that that figure will double to approximately \$6 trillion per year on average through 2021.

Extant literature have discussed cybercrime in various perspectives, for example, its impact (Ananthakrishnan, Li, & Smith, 2015; Riek, Abramova, & Böhme, 2017), detection and defensive measures in the fight against cybercrime (Biswas, Pal, & Mukhopadhyay, 2016; Tapanainen, 2017; Zhang, Lee, & Wang, 2016), law enforcement, strategies and prevention (Alanezi & Brooks, 2014; Ju, Cho, Lee, & Ahn, 2016; Kolini & Janczewski, 2017). Even though these studies are only a few of what exists in the respective themes, a preliminary review indicated that very few of these studies had been done with particular focus on the socioeconomic drivers behind the commission of cyber offences especially in developing economies.

According to the ITU (2012) The term “cybercrime” is used to describe a range of offences including traditional computer crimes, as well as network crimes. As these crimes differ in many ways, there is no single criterion that could include all acts mentioned in the different regional and international legal approaches to address the issue, while excluding traditional crimes that are just facilitated by using hardware. Such crimes may include hacking, bullying, identity theft, confidence romance, advanced fee fraud, among others. Riek and Böhme (2018) for instance posited that losses as a result of cybercrime are driven mainly by scams and extortion in Germany and identity thefts in the UK. Italian, Estonian, and Polish consumers on the other end, lose considerably less money to cyber-criminals, even though they spend less money and time on protection. Whereas this development is relative to the western countries, the situation is not entirely different in Africa. Cross (2018) for instance asserts that Nigeria has become synonymous with online fraud, with advance fee fraud (AFF) dominating in recent decades.

DOI: 10.4018/978-1-5225-9715-5.ch005

Consequently, Nigeria ranked as the leading State in the region for the conducting of malicious Internet activities (Aransiola & Asindemade, 2011; Longe & Chiemeke, 2008; Quarshie & Martin-Odoom, 2012). That notwithstanding, many countries in the continent have developed legislation to fight cyber-threats. They have also strengthened enforcement measure as well as engage private sector efforts to enhance cybersecurity (Kshetri, 2017). In East Africa for example, a task force comprising government, industry and civic groups have been set up to deal with cybersecurity at the three levels of legal, policy, and regulation. While the Economic Community of West African States (ECOWAS) have initiated policies in capacity-building, prioritising cybercrime issues and developing networks across the borders as a definite way in fighting cybercrime (Quarshie & Martin-Odoom, 2012).

Ghana, our country of focus formulated two policies; ICT for Accelerated Development Policy of 2003 and the National Telecommunications Policy of 2005 both aimed at facilitating the country's development into an information society. The sub-Saharan country also has a vision of developing its economy to a middle-income level, and thus requires the development and exploitation of ICT both as a business sector and as an enabler of other sectors (Frempong, 2012). Further, Internet penetration in the country for the past few years has been on the ascendancy. Hootsuite (2018) for instance reports that about 10.11 million representing 35% of the population are active internet users with 32% active phone internet users. With this statistics in perspective, it will arguably not be out of place to contend that as more and more people get access to data, we expect cases of cybercrime to escalate (National Communications Authority, 2017). With this backbone, this chapter seeks to answer these research questions. First, what are the motivating factors to the commission of internet crimes in developing countries and second, what are the perceptions of stakeholders in the fight against cybercrime?

This paper is in eight sections with the first giving a broad overview of cybercrime by way of introduction, review of cybercrime literature and the theoretical foundation of cybercrime. The fourth and fifth sections explain the methodology of the research and further presents the findings of cybercrime in Ghana. The final two sections include the conclusion and the summary of the findings indicating implications for research, practice and policy and pointers for future research.

LITERATURE REVIEW

There exists a significant volume of research on cybercrime and its attendant effects on countries and the social stigmatization that accompanies them. These literature cover a number of relevant themes which include but not limited to the fight against cybercrime (Cassim, 2011; Adomi & Igun, 2008; Malgwi, 2005; Jamil, 2012; Huey, Nhan & Broll, 2012), credit card fraud or financial crimes (Barker, D'Amato & Sheridan, 2008; Gottschalk, 2010; Prabowo, 2012), Advance fee fraud (Durkin & Brinkman, 2009; Dobovsek, Lamberger & Slak, 2013; Salu, 2005), Law enforcement (Davis, 2012) and Confident Romance and dating (Fair, Tully, Ekdale & Asante, 2009).

Onwuegbuzie, Leech and Collins (2013) postulate that a thorough, sophisticated literature review is the foundation and inspiration for substantial, useful research. It is therefore helpful in two ways; thus, it does not only help researchers glean the ideas of others interested in a particular research question, but it also lets them read about the results of other (similar or related) studies. The definition of the spectrum of cybercrime has also been an issue of contention especially considering the dynamics of the phenomenon (see Table 1) (ITU, 2012). Adomi and Igun (2008) defined cybercrime as *any unlawful conduct carried out with the use of computers, electronic and ancillary devices*. Cassim (2011) also contends that

Table 1. Definitions and factors considered

Author (s)	Definition/characteristics of cybercrime	Internet fraud	Computer hacking	Cyber piracy	Spreading of malicious code	Others
Cassim (2011)	On one hand, a computer may become the 'object' of a crime when a computer hardware or software occurs. On the other hand, a computer becomes the 'subject' of a crime when it is used as an 'instrument' to commit traditional crimes.	✓	✓	✓	✓	✓
(Adomi & Igun (2008)	Any unlawful conduct carried out with the use of computers, electronic and ancillary devices	✓	✓		✓	✓
Loader & Thomas (2013)	Computer-mediated activities which are either illegal or considered illicit by certain parties which can be conducted through global electronic networks.	✓	✓	✓	✓	✓
Chung, Chen, Chang, & Chou (2006)	Illegal computer-mediated activities that often take place in the global electronic networks.	✓	✓	✓	✓	✓
Longe et al., (2009)	Cybercrime refer to misconducts in the cyber space as well as wrongful use of the internet for criminal purposes	✓			✓	✓
Gordon & Ford (2006)	Any crime that is facilitated or committed using a computer, network, or hardware device	✓*	✓		✓	✓
Kshetri (2009)	Criminal activities in which computers or computer networks are the principal means of committing an offense	✓	✓			✓
ITU (2012)	a range of offences including traditional computer crimes, as well as network crimes.	✓	✓	✓	✓	✓

Cybercrime, also known as 'computer crime' appears to have no precise definition. On one hand, a computer may become the 'object' of a crime when a computer hardware or software occurs. On the other hand, a computer becomes the 'subject' of a crime when it is used as an 'instrument' to commit traditional crimes such as fraud, theft, extortion, 'new' types of activities such as denial of service attacks and malware, identity theft, pornography, or copyright infringement.

For the purpose of this research, this chapter will define cybercrime as *any unlawful conduct executed with the aid of any computing device or other forms of ICTs*. This includes but not limited to advance fee fraud, cyber harassment, illegal online shopping, Credit Card Fraud, Confidence Fraud/Romance, child pornography et cetera.

It must however be well noted that in as much as developing countries are touting the potential of the internet for national development, they are also cautious of the potential dangers posed by its misuse. The negative impacts of cyber fraud are both economic and social (Durkin & Brinkman, 2009). Further, from the perspective of ICT for development, it is not misplaced to say that cybercrime portends some dangers and have the potential to stall the developmental contributions accruable from a well-harnessed ICT adoption, diffusion and usage in Sub-Saharan Africa (Boateng, Olumide, Isabalija, & Budu, 2011).

Several studies have been done with the Sub-Saharan region in focus. These studies follow quite a wide range of themes (some of such have been indicated in Table 2). Inasmuch as these studies are exhaustive, there is a lack of concentration on the roles IT skills play in the commission of a crime. Aransiola and Asindemade (2011) in studying new strategies employed by cybercriminals in Nigeria identified imperceptible aids including the use of ladies as collaborators, collaboration with security agents and bank officials, local and international networking, and the use of voodoo. A similar study by Warner (2011) sought to give account on the broad overview of Ghanaian cybercrime, focusing on its genesis, the various incarnations of national scams and the state-level reactions. The study claimed that most Ghanaian believe cybercrime was imported from Nigeria as a result of the influx of Nigeria Nationals residing in Ghana; geopolitics. Secondly, Warner (2011) similarly to Tade, (2013) identified that the delayed success rates in *yahoo yahoo*, the untiring clampdown of the Economic and Financial Crimes Commission on cybercriminals, group rivalry and the activities of the media in enlightening the public accounted for the search for a more speedy way of increasing cybercrime victimisation hence the *techno-spiritual paradigm of Sakawa*. Finally, Warner (2011) identified that perpetrators of cybercrime in Ghana justified their actions with the assertion that there is nothing wrong with the act but a sort of redemptive project of social justice; vengeance for centuries of historical injustices perpetrated by the West against Africans. Again, even though the findings by Warner (2011) gives grounds to further studies in cybercrime especially in Ghana, the study dwelt on secondary data; the data collected did not include perpetrators of cybercrime but the views of individuals on cybercrime in Ghana.

Despite the enormous contributions of these studies, there seem to be a gap in the understanding of cybercrime from the viewpoint of cybercrime perpetrators *vis a vis* law enforcement agencies and secondary stakeholders. Further, theories employed in studying computer related crimes remain sparse considering the dynamic nature of the phenomenon. Boateng, Olumide, Isabalija and Budu (2011) underscored the need for future studies to explore how social theories in criminal studies can help in understanding behaviour and intention of both the victims and perpetrators in cybercrime. This chapter provides useful insights in response to these gaps.

THEORETICAL FOUNDATION

A number of criminological and social theories have been postulated to explain criminal activities and the behaviour of conventional criminals. However, empirical research to validate these theories in the context of cyber activities and the application of these theories to cybercrime are sparse in literature (Wada, Longe, & Danquah, 2012). These include but not limited to Routine Activity Theory (Cox, Johnson, & Richards, 2009; Jansen & Leukfeldt, 2015; Olayemi, 2014; Reyns, 2013), Space transition theory (Danquah & Longe, 2011; Jaishankar, 2008), Protection motivation theory (Jansen & Leukfeldt, 2015). Inasmuch as these theories are relevant to cybercrime studies, there have also been calls for future studies to explore how social theories in criminology can assist in understanding the behaviour and intention of both the victim and perpetrators in cybercrime (Boateng et al., 2011; Holt & Bossler, 2014; Jaishankar, 2008).

Table 2. Cybercrime studies in Ghana and Nigeria

Article	Country and Perspective	Theme / Theory	Findings
Tade (2013)	Nigeria Student [Cybercrime] fraudsters	Cybercrime and spirituality Theory: <i>Space transition theory</i>	The delayed success rates in yahoo yahoo, the untiring clampdown of the Economic and Financial Crimes Commission on cybercriminals, group rivalry and the activities of the media in enlightening the public accounted for the search for a more speedy way of increasing cybercrime victimisation.
Quarshie & Martin-Odoom (2012)	East and West Africa Content Analysis	Legal and regulatory frameworks Theory: <i>Not Considered</i>	The research revealed that the way forward is for Africa to learn from the experience of developed countries in fighting cybercrime. The fight against cybercrime requires a coordinated effort among all stakeholders such as government bodies, educational institutions, business organizations and law enforcement authorities.
Olayemi (2014)	Nigeria Law Enforcement Agencies, Governmental Institution	Legal and regulatory frameworks Theories: <i>Routine Activity Theory</i> <i>Structural Functionalism Theory</i> <i>Marxian Theory</i> <i>The Theory of Technology-Enabled Crime</i>	Laws to combat cybercrimes are useless if law enforcement agencies do not have the education and training necessary even to operate a computer. Judges must be well trained as well
Aransiola & Asindemade (2011)	Nigeria Perpetrators	New cybercrime strategies Theory: <i>Not Considered</i>	Most cybercrime perpetrators in Nigeria are between the age of 22 and 29 years who were undergraduates and have distinctive lifestyles from other youths. Their strategies include collaboration with security agents and bank officials, local and international networking, and the use of voodoo, thus traditional supernatural power. Findings also indicated that most perpetrators of cybercrime were involved in online dating and buying and selling with fake identity among others.
Warner (2011)	Ghana Perpetrators*	Geopolitics Techno-spiritual paradigm (Sakawa) Justified Philosophy of Thievery Theory: <i>Not Considered</i>	Sakawa boys justify their duping of Westerners by claiming that it is pointed retribution for centuries of historical injustices perpetrated by the West against Africans. The rise and proliferation of the techno-religious phenomenon of Sakawa is another increasingly embedded, yet underreported aspect of the practice of Internet fraudulence in Ghana.
Boateng, Olumide, Isabalija, & Budu (2011)	Ghana Internet Café Operators Law Enforcement agencies Lawyers Banks	Forms and implications of cybercrime Theory: <i>Not Considered</i>	Cybercrime is fast gaining grounds in Ghana and the agencies responsible for investigating, controlling and apprehending online criminals lack the technical knowledge needed to tackle the problem. In Ghana, the perpetrators are young and have some degree of technical competence to commit computer-related crimes.

The Routine Activity Theory

The Routine Activity Theory (RAT) postulated by Cohen and Felson (1979) is an ecological approach to crime causation, and the accessibility, location, and presence or absence of environmental characteristics, and certain types of people are what proves predictive of criminal behaviour. It presupposes that for a crime to take effect, three required elements must be present. First is the motivated offender, second, a suitable target; The suitable target here refers to a person, object or place and finally, the absence of capable guardians; a deterrent like police patrols, security guards, neighbourhood watch, door staff, vigilant staff and co-workers, friends, neighbours and CCTV systems (Wada et al., 2012) (see Figure 1).

Figure 1. The routine activity theory of crime

The RAT even though was originally postulated as a traditional crime theory has been adapted and used in various cybercrime studies (e.g. Cox, Johnson, & Richards, 2009; Reyns, 2013; Xiao, Chan, Cheung, & Wong, 2016; Yar, 2005) because of its robustness. Table 3 illustrates the various forms of cyber offences the theory has been used to study as well as the consideration as sole or combined theory.

Despite these advancements in literature, focus on the technological aspect of the RAT is sparse as most scholars employ the use of the theory as is, or combine it with other theories to answer peculiar questions. This therefore perhaps prompted some researchers (Eck & Clarke, 2003; Holtfreter, Reisig, & Pratt, 2008; Pratt et al., 2010) to explore the possibilities of using the theory to explain opportunities for crimes at a distance (Reyns, 2013). Eck and Clarke (2003) for instance argued that the traditional Routine Activity Theory proposed by Cohen and Felson (1979) *could be expanded by making one modification*.

Table 3. Routine activity theory in cybercrime studies

Studies	Forms of cybercrime	Usage	Other theories
Olayemi (2014)	General	Combined	• Structural Functionalism Theory • Marxian Theory • The Theory of Technology-Enabled Crime
Kigerl (2012)	General	Sole	N/A
Reyns (2013)	Identity Theft	Sole	N/A
Reyns, Henson, & Fisher (2011)	Cyberstalking	Sole	N/A
Navarro & Jasinski, (2012)	Cyberbullying	Sole	N/A

Leukfeldt (2014)	Phishing	Sole	N/A
Reyns & Henson (2016)	Identity Theft	Sole	N/A

Source: Literature synthesis

In their view, if the target and the offender are part of the same geographically dispersed network, then the offender may be able to reach the target through the network. Eck and Clarke (2003) further posit that networks do not only facilitate interaction at a distance; they can also increase the speed of distant contacts. For instance, whereas traditional crime under the routine activity theory may unfold slowly and may occur over a long period, the internet can increase the speed with which the same sorts of frauds can unfold. Tillyer and Eck (2009) advanced this argument by establishing that the RAT focusses on offenders making contact with targets at physical locations, which therefore creates a void in studying crimes that occur at a distance. Tillyer and Eck (2009) finally suggested that either the routine activities theory is limited to place-based crimes or it needs revision.

These developments have arguably made it imperative to conceptualise the RAT in terms of current trends in technologies and technology related crimes. For instance, the three elements of the RAT may exist; the motivated offender, the target and the absence of a deterring factor but in the midst of all these, what role does knowledge in technology play in the triad? This further translates into investigating the interrelationship between technology and the constructs of the RAT. Eck & Clarke (2003) in critiquing the theory suggested the inclusion of networks as represented in Figure 2. However, this chapter conceptualises the theory with the integration of Eck and Clarke (2003) network to the original theory; motivated offender, suitable target, absence of a capable guardian and Network. To this end, the study will first unveil the categories of people who fall under the offender's construct. Secondly, concerning the victims of cyber offences as postulated by the theory, the chapter will solicit the categories of victims that the offenders target and their characteristics. This will enable the researchers to understand the victims from the perspective of the offenders. The third is to understand the role of guardianship in forestalling cyber offences. This will be done by engaging law enforcement agents and law practitioners. Finally, with respect to technology and networks which form the basis of our arguments, the chapter will seek to bring to bear the facilitating roles played by emerging technologies and the commission and prevention of internet crimes.

Figure 2. Systems problems

METHODOLOGY

1

This section presents the methodology adopted for this chapter. It covers the research paradigm employed as well as strategies for data collection and the mode of analysis. In order to achieve the research purpose of this chapter, the critical realist stance was adopted. Critical realism enables the researcher to unearth the mechanisms that cause events to occur (Mingers, 2004). This lays a strong foundation for this study, in that it goes beyond the generalization of all IT related crimes as cybercrime, to a detailed exposition of the social and economic motivations of the offender as well as the technological aids. With this in perspective, there is therefore the need to understand how CR can be employed in conducting such a study.

To address this, this chapter adopted a retroduction research strategy which is peculiar to the critical realists (Scott, Zachariadis, & Barrett, 2013; Strong & Volkoff, 2010). Retroduction allows researchers to move between the knowledge of empirical phenomena as expressed through events to the creation of explanations (or hypothesizing) in ways that hold “ontological depth” and can potentially give some indications on the existence of unobservable entities (Downward & Mearman, 2006). Retroduction according to (Danermark, Ekström, Jakobsen, & Karlsson, 1997) poses one fundamental question. In this case, *what properties must exist for cybercrime to exist and to what extent is cybercrime?* The dexterity of retroduction lies in its ability to aid a researcher to establish generative mechanisms for phenomena such as cybercrime to exist. Taking this as one’s starting point, retroduction becomes a matter of trying to attain knowledge about what internal relations make cybercrime what it is (Danermark et al., 1997).

Three main phases manifest in employing the retroductive research strategy for a study. At the initial stage, the authors began by examining the observed events and connections in the social phenomena. At this level, the researcher is required to conduct a thorough literature review on cybercrime to bring to bear the theoretical and conceptual underpinnings which have been used to explain cybercrime in previous studies (see section 1.2). Next, the authors hypothesized the presence of real structures and mechanism and how they describe the observed relationships. In the critical realist’s viewpoint, this is done through theorising a model of an underlying mechanism which might have produced patterns seen in the data and then works backwards from the data towards verifying or otherwise that model (Mason, 2002). This step has been well outlined in 1.3 of this chapter by first adopting the routine activity theory of crime and thence conceptualising it to include networks as pointed out by Eck and Clarke (2003). Finally, the third step is to establish that the structures and mechanisms postulated in section 1.2 operate and exist. The researcher then needs to select suitable data collection methods that support the purpose of the study.

Case Selections

For the purpose of studying contemporary socio-technical phenomenon to uncover the causal mechanisms and contextual factors that combined to generate them, case study research is well-suited to conduct critical realist research (Wynn & Williams, 2012). Boateng (2014) suggests that case selection requires the researcher to be knowledgeable about the characteristics of the case before the beginning of the main case study. With this in mind, a pilot study was conducted in March 2017 and the main study between August and September 2018. Due to privacy and the nature of the study, some respondents during the pilot study opted to hold interviews via phone conversation rather than a face to face interaction. The rest of the interviews were then scheduled at the internet café where the respondents occasionally operate. After the pilot study, four out of a total of seven respondents agreed to participate in the study. The

four were a group of young men who operate together from the same room (which they refer to as ‘the office’). A plausible reason for the other three’s refusal to participate could be that one of them is in the process of withdrawing from the act and in undergoing personal rehabilitation. The other two’s refusal was on the grounds of privacy. The selection of one case for this research stems from the fact that unlike positivist research which seeks statistical significance, a CR-based case study research attempts to develop explicit causal explanations of the complex social, organizational, and inter-organizational phenomena encompassing the IS field (Wynn & Williams, 2008a).

Finally, in order to control the influence of various biases on the research process and the generated results (Wynn & Williams, 2008b) this chapter did not compromise on data triangulation. This was to aid in testing validity through the convergence of information from different sources (Carter, Bryant-Lukosius, DiCenso, Blythe, & Neville, 2014). In this regard, both internal (interviews with the respondents at various times as well as document examination) and external triangulations (interviews with other stakeholders such as officers at the cybercrime unit of the Ghana Police Service, Bankers and internet café operators) were conducted. Further, methodological triangulation through participant observation and website, newspaper reports and document analysis was employed.

Data Collection and Analysis

Both unstructured and Semi-structured interviews were the primary data collection methods employed for this chapter. This was done through several planned and unplanned interviews with the core respondents; perpetrators. In each instance of the interviews, the researchers spent between 45 minutes to an hour with the respondent. However, the researchers asked other spontaneous questions via phone conversation to ascertain clarifications for data collected earlier. The recognised leader of the group holds a senior secondary school certificate with somewhat IT training skills from an IT college in Ghana. He has been practising the act since 2008 and that is sole means of living. Two among the other three also hold senior secondary certificates while the last among them dropped out of secondary school.

Upon obtaining information from the perpetrators the authors then followed up by interviewing six internet café operators, eight bank staff from two major banks in Ghana (one local and one foreign-owned banks), eight lawyers and officials from the cybercrime unit of the Ghana Police Service. This was to verify and obtain their perspectives on the data collected from the case subjects. All interviews were recorded and transcribed for coding purposes. As CR emboldens the use of multiple sources of data collection of perspectives of mechanisms and structures which underpin readily observable events, the researchers conducted observations of interactions among case subjects and their victims.

Mode of Analysis

Critical realism as applied in social research seeks to penetrate social phenomena and disclose deep social structures (Brown, Slater, & Spencer, 2002). Abstraction entails separating the intrinsic and constituent properties in a social phenomenon from contingent ones to find what in the phenomenon makes it what it is and not something else (Boateng, 2014; Danermark et al., 1997). After the data collection, themes (focusing on the events/forms of cybercrime) were generated from the transcribed interviews. Each theme was examined as a critical event towards achieving an outcome. Analytical techniques were drawn from Miles and Huberman (1994) qualitative data analysis approach which identifies three other stages after data collection; data reduction, data display and drawing conclusion and verification.

FINDINGS, ANALYSIS AND DISCUSSION

1

This section presents the case finding of the chapter. For purposes of confidentiality, the name of the leader will be referred to Chief informant and their collective name as *the Group*.

Cyberculture Among Ghanaian Youth

As indicated in the foregoing paragraphs ICT and for that matter internet penetration in Ghana has been on the ascendancy. Prior to this, internet cafés in the country became extremely popular in Ghana possibly to afford citizens who cannot afford dedicated internet services the opportunity to temporary use the cafés at a fee. An Earlier study by Burrell (2012) on internet café patronage and usage suggested that the typical Internet user in these cafés – young, educated but not to a university level, and usually not from affluent families – had a different relationship to ‘information’ than older, university educated, and affluent users. The two groups of people identified both have different purposes of using the internet cafés. According to Burrell (2012) the younger groups spend more time in the cafés and usually come in groups pursuing entertainment and occasionally playing computer games. University graduates and students on the other hand patronized the internet cafés to research and acquire information.

The internet cafés served as place where young people are if at all immune to the supervision of their parents. This therefore afforded young patrons of internet cafés the opportunity to gang up at nights after school hours at the cafés for conversations and sometimes arguments about subjects of interests. By so doing, harmless thoughts of looking for pen pals are developed into seeking partners at online dating platforms and thence developing petty cyber-deviant skills. It is worth noting that some cyber deviances are learnt through shared opinions of peers in the cafés. Examples of cyber deviant behaviours among youthful café patrons include identity theft, credit card fraud and online shopping, romance scams among others. It is common knowledge among the youth who patronize the cafés that there are specializations in the abovementioned forms of cybercrime. As such they lend their services among themselves for percentages of the proceeds that emerge from such ventures. It is against this backdrop that a group made up of four members emerged. The ensuing sections present an elaborate picture of one of such group.

Group Profile

The *Group* which began informally with a workforce of seven people in 2015 currently houses four core working group with one female affiliate. At inception, the members of the group patronised the same internet café in their neighbourhood; however, at the time, they operated in *each one for himself* situation. Chief Informant, the leader of the group began engaging in internet crimes in 2008 while in senior high school. He graduated in 2012 and furthered in a reputable IT training school in Ghana. He dropped out of the IT training in 2013 after becoming disappointed in the program. Among the other three in the group, one dropped out of senior high school while the other two completed. The group operates in the Chief Informant’s room. Though the room is not explicitly furnished for office/scam duties, they have acquired two computer desks and office chairs to warrant comfort of operations. At the time the computer desks are occupied, the rest work from a ‘*three in one*’ living room chair and the table placed at the centre of the room. Table 4 below summarises the educational level of the group members as well as their years of experience in perpetrating cybercriminal activities.

Table 4. Education level and cybercrime experience of group members

Pseudo-names	Age*	Educational Qualification	Years of Experience	Formal Work experience
Chief Informant	27	Senior High School Leaver with partial IT training	Since 2008	-
GM2	25	Senior High School Leaver	Since 2011	-
GM3	25	Senior High School Leaver	Since 2011	Electrician
GM3	26	Dropped out of senior high	Since 2013	-

*Ages as at the time of data collection

Prominent among the many activities conducted by the group include confidence romance scams, credit card (generation) fraud, identity theft and online shopping. The scheme of operations in the aforementioned activities has been outlined in the following sections.

Confidence Romance Scams

The ultimate motive of the group is to acquire wealth and as such confidence romance seems to be top of the agenda in that regard. This activity commences by first creating attractive profiles in social media sites especially online dating platforms. In this instance, identities provided are either a rich old man (60 years plus) seeking equal financially sound middle-aged female ‘lover’ or a young philanthropist and financially independent female (usually between 25-35 years) seeking equally rich old men for relationships. They use appealing descriptions such as globetrotter, civil engineers, international social worker undertaking humanitarian projects in Africa among others (see Figure 3).

Such self-descriptions tend to appeal more to women mostly single or divorced who are seeking to begin new relationships. It must however be noted that the scammers create multiple accounts, stalk and send friend requests to one particular target until he/she falls for one of the fake identities (see Figure 4). The scammers begin forging appealing stories about themselves to get the targets glued to the friendship. Here the motive of the scammers is to surge intimacy with the victim with the intention of building trust. In efforts to achieve this, both parties introduce themselves and chat about their past and how they intend to rebuild a lasting relationship.

Sometimes I tell them my former wife left me because I was travelling too much...but now that I want to go back to my country and settle, I need someone as sweet as you. (The Chief Informant)

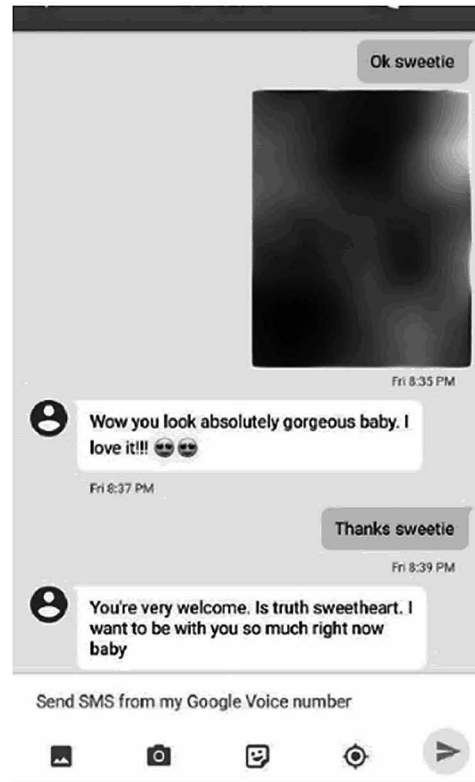

At this stage, the scammers maintain a perfect storyline in order not to lose the relationship. In the words of the Chief Informant, *you have to correctly remember the story for each client*¹.

After establishing trust at this level, the scammers go the extra mile to purchase flowers from online sites to be sent to the would-be victim thereby instilling confidence in them that the relationship is for real. This then opens the way for the exchange of gifts between the two.

After some months of engaging each other, *it is time* for the ‘scammer’ *to go back home* which then requires them to forge a new story inching to the close of the deal. Here the scammer may create a tragic story which will compel the victim to give in to the scam finally.

Figure 3. A snapshot of a conversation between a scammer and would-be victim

1

So, I was robbed on the day that I had to leave back to America by the taxi driver who drove me to the airport. So, I am stranded at the airport right now... even at the time I am chatting with her, I am using the airport police's computer. So, she should send me money for airfare back home (The Chief Informant).

At this stage of the relationship, smart victims or victims who have a wind of how cybercriminals operate abruptly ends the relationship. However, those who fall prey send the monies for the 'scammer' to come home for them to start their family. Here, the scammer requests the victims to send the funds through their assistant since he (scammer) has lost all belongings due to the robbery. The newly introduced assistant in real life in most cases is the real identity of the scammer or the female accomplice.

The scammer upon receiving the money ends the relationship and deletes all particulars, pictures and profiles relating to that particular account.

Oh! Sometimes when I receive the money, I tell her to wait for me at the airport and that is the end of it (The Chief Informant).

Credit Card Fraud, Identity Theft and Online Shopping

Data collected during the interview points to the direction that most scammers in Ghana knowing or unknowing engages in multiple internet crimes at a point in time. This emanates from the fact that most of the crimes perpetrated by the scammers are interlaced (see Figure 5). The following paragraphs describe the crime and their interrelationships.

Figure 5. Interrelationship of crimes by scammers

Scammers in registering for exclusive online dating communities are compelled to make payments thereby having to resort to *credit card fraud*. Here, there are various ways scammers do this but only two will be discussed. First, there are credit card generating websites where these scammers generate credit card numbers randomly (see Figure 6). After which they are required to find identities behind the cards. These numbers are then used to register on dating sites to lure women seeking dating opportunities. It must however be noted that registrations on dating sites are to a large extent not intentions to use the site but have linking determinants. Thus, scammers need to test the validity of the credit cards as well as find vulnerable women either to lure or use as conduits (unknowingly) for their fraudulent activities.

... if I want her to believe me more, I buy things with the credit card for her so that she will know that I am original ... As for her, she don't know but me, I am testing the card (informant 3).

The second method scammers device in getting credit card numbers is buying from hackers. These are faceless people who hack into bank details and sell cards at a cheaper rate to scammers. In this case, scammers buy bitcoins, perfect money, web money et cetera with their native currencies and use the internet money to buy hacked credit cards from the hackers. The risk involved here is that the credit cards may or may not contain money. However, in instances where the cards contain some amounts of money, the scammers use the real details of the cards to buy from online retail shops such as Amazon, Apple, Walmart, Bestbuy et cetera but the difficulty in this venture is the blacklisting of some countries including Ghana by these shops. This then compels scammers to resort to alternate means and that is by finding lovers/clients on online dating sites who may later fall for their tricks. At this stage, the scammer engages the interest of the client for a long period to win his/her trust. After the trust is won, the client (would-be victim) is told the scammer is organizing a charity initiative in Africa, and that donors would be sending donations to him in Africa however they (the donors) are unable to do so because most shops in the states do not ship directly to Africa. This in effect implies the lover would have to receive all donations and ship them to the home country of the scammer in the name of his personal assistant. It is worth noting also that some clients do not send the donations. Such victim turned scammers also terminate the relationships with the Ghanaian scammers.

Figure 6. Snapshot of Elfqrin credit card generating page

... That one is for JSS people ... we buy the cards from the black market with bitcoin... some of the cards can contain enough money and others too, small money... it is like gambling (Chief informant downplaying the first method).

Other Stakeholder Perspectives of Cybercrime in Ghana

In our quest to triangulate data from the field, eight bankers, six café operators, eight lawyer and officers at the cybercrime unit of the Ghana Police Service were interviewed.

Bankers

The minimum years of service from bankers interviewed was three years. In Ghana for instance, the requirements for one to withdraw or redeem sums of money from international money transfer is any national identification card such as Voter ID, Passport, Health Insurance Cards, Drivers' license. Secondly, recipients are required to fill a form indicating his/her full name, name and address of the sender, the amount he/she is redeeming and finally assess codes. However, there are instances where recipients are required to answer random questions at the request of the sender

When asked if the banks had ever suspected fraudulent withdrawal of monies from their banks, one respondent responded on the affirmative.

Yes, we know when they withdraw money suspected to be fraud monies.

The follow-up inquired of their pre/post-withdrawal actions but the respondent said

There is nothing we can do about it because they present every legal document and fulfil all mandate required of them. In short, we lack the legal evidence to deny them of their withdrawal. One of their tricks is also that they don't come themselves. They send ladies.

Another follow-up was why the bank does not report the suspects for investigations to continue from there. The respondent answered that

Like I said, first of all, we don't hold any legal evidence. Secondly, it will take a long while to conclude. It is usually difficult following such cases especially when the person has met all the requirements to withdraw money.

Regarding efforts to combat cybercrime in Ghana, respondents indicated that on the side of the banks, they ensure maximum security on their online platforms. Therefore, when one makes a transaction online, a pin is sent to his/her phone for confirmation.

Even before you can access another persons' online banking interface, there is a verification code that is sent to the person's phone. So, if it's a third party who is doing that... so it's now a two-way thing. If you don't have your mobile phone, you can't do a transaction online because a verification number will be sent to your phone. Formerly it wasn't like that but because of our reputation, we are trying to bridge all those loopholes and all those gaps to make the system tighter.

Bank respondents finally pointed out to the fact that *the police should be equipped technologically to be able to assess intelligence on cybercrime activities.*

Internet Café Operators

With regards to public internet cafes, the operators indicated that the proliferation of mobile telephony and internet data penetration had disadvantaged their operations. However, cybercriminals are forced to come to their cafés to perform their activities because they do not like operating without pressure. For instance,

Because they buy café time, they need to finish what they are doing before the time runs out. So, they like working under pressure.

They also indicated the multi-stakeholder awareness in the cybercrime phenomenon. They pointed to the fact that the Banks, Police, ISPs and International Shipping agencies are *aware of the thing going on. This thing is no longer illegal oooh. Don't be lied to. I have seen it before; a shipping company's official was tipped GH¢1000.00 for the clearance of a consignment. Who says the police are not aware (he inquired)? A cousin of mine was chased for driving a DV(defective vehicle) plate car but he tipped them for them to leave him. It has become legal but people have turned their blind eyes to it.*

Café operators finally believed, *unemployment* is a major contributing factor to the cybercrime phenomenon. *There are those who want to come out of it but there is an issue with what they are going to do after discontinuing their current venture.*

Legal Practitioners' Perception of cybercrime

The questions in this perspective sought to find out reasons lawyers will or will not defend cybercriminals as well as whether there are laws in the statute books to address this type of crimes. However, they are unaware if there are current state policies on cybercrime. The respondents pointed to the electronic communications act as well as the criminal code of Ghana. On jail term for cybercriminals, one criminal lawyer who had defended a client on sim-box fraud indicated that

One is not guilty until proven guilty and when found guilty, the various acts I mentioned (Electronic, data protection and taxation) provide for custodial sentences where applicable.

Regarding law enforcement and the lack of prosecution of cybercriminals, a litigation lawyer said,

Well, my personal experience with law enforcement agencies with respect to cybercrime is that, cybercriminals are friends with the police... I think that cybercrime is thriving because the police benefits from it. Once they benefit, there is nothing they can do about it.

This assertion corroborates with the internet café operator's claim that *the police are aware of the crime but little has been done to tackle it.*

Cybercrime Unit of the Ghana Police Service

Considering the rate and scope of cybercriminal activities in Ghana, the Ghana Police Service in August 2015 separated the Cybercrime Unit from the Commercial Crime Unit of the Ghana Police Service. Data from the field interview with the officers at the Unit suggested that several elements contribute to the presumed slow efforts to attack cybercriminals. For instance,

Thousands of cases go unreported. Sometimes, the public feels guilty for falling prey to cybercriminals. We are trying to educate our people to empathize with them and not to ridicule them. People do not also know where to report cybercrimes since it's not a conventional crime.

The Officers also pointed out that *we are adequately resourced knowledge-wise. But technologically, we need to be resourced. Even though we rely sometimes on forensics, I must say we are not adequately resourced technologically.*

On laws and policy documents that are used to prosecute cybercriminals, the Official confirmed the claims of the lawyers that,

We rely mostly on the electronic transactions act, the data protection acts and the criminal offences act but to the extreme, we sometimes use a joint charge by combining the acts.

Finally, the police also called for a multi-stakeholder venture in the fight against cybercrime. These must include the ISPs...

Even though IP addresses are no more static, how prepared are the ISPs to furnish the police with such information.

... the banks must be prepared to report suspicious account revamps to the financial intelligence centre which in-turn investigates and report to us.

DISCUSSION

As illustrated from Figure 7 above, the outcomes of the phenomenon which the researcher seeks to investigate is the event. In the instance of this research, the authors identified the events like the various forms of cybercrimes in Ghana i.e. credit card fraud, confidence romance, identity theft and online shopping (see Figure 8). Even though these events are seen to be independent of each other, cybercriminals combine them as strategies towards an ultimate objective of acquiring wealth. The events are triggered by mechanisms which are dependent on structures (embodied entities) and conditions to occur. Entities or objects provide the essential theoretical building blocks for critical realist explanation and can be such things as organisations, people, relationships, attitudes, resources, inventions, ideas and so on. They can be human, social or material, complex or straightforward, structured or unstructured. Entities have causal powers and liabilities (Easton, 2010). A structure according to (Sayer, 1992:92) can be defined as sets of internally related objects or practices. Entities will usually be structured (Easton, 2010). For

Figure 7. A critical realist view of causation

instance, the case under study consist of a set of entities (people, resources, processes etc.) all of which can affect one another. The aim of a critical realist is to seek causal explanations to a phenomenon i.e. by identifying entities and mechanisms that combine to generate events within specific conditions. Thus, to ask the question “What caused the events associated with cybercrime to occur”. To better explain this, the data has been reduced and displayed in Figure 8 to identify the key entities and conditions which connect and combine within specific mechanisms to generate particular events.

It can be recalled that the routine activity theory postulates three main elements to be present to classify an activity as a crime; motivated offender, suitable target and the absence of a capable guardian. Data collected indeed confirmed this postulation however, our findings pointed to the fact that there exist other factors/elements which contribute in order for cybercrime to take place possibly in the context of our study.

Figure 8. A critical realist view of causation of events

Motivated Offender

The findings from this empirical study suggested that the cybercriminal space is male-dominated. Even though perpetrators sometimes use female accomplices as decoys in withdrawing huge sums of monies from the banks, the majority of the work are done by the male counterparts. Further, the findings suggested that perpetrators are mostly in their young adulthood. For example, a news items read

...The suspects, believed to be part of a wider cybercrime syndicate made up of Nigerians and Ghanaians, attempted transferring a whopping GH¢326 million from the vault of Universal Merchant Bank (UMB) electronically... The ages of the all-male suspects range from 25 to 49 years (Ghana News, 2018).

These findings do not differ from earlier studies which suggest that the perpetrators are young (Aransiola & Asindemade, 2011; Boateng et al., 2011) and that women also do also assist their boyfriends when he is using a female identity (Aransiola & Asindemade, 2011).

The findings of this study finally suggest that cybercrime perpetrators in Ghana arguably include young people who may have been exposed to some level of IT skills in schools. Offenders may as well include school dropouts also with basic IT skills.

Suitable Targets

With regards to the targets of cybercrime perpetrators in Ghana, there seem to be interweaved interests in the target of crimes. For instance, while the offenders may engage a romance victim for a period of time, the scammer's attention is particularly directed at making purchases on online stores through their victims.

The findings of the current study tend to appreciate two of the four-fold (VIVA – Value, Inertia, Visibility and Accessibility) constituents properties of targets classified by earlier studies i.e. the Value and Visibility of targets (Leukfeldt, 2014; Yar, 2005).

With regards to value, data collected was suggestive that place high premium in their targets so much so there are occasional scuffles at public internet cafés. For instance, a café operator recalled that,

There was once a fight here because one guy ran away with another's client... He asked the guy to chat the client for him and later found out that the guy was chatting the client privately on another account.

In that regard, the search for romance victims is tactical in that scammers search for rich and financially sound people desperately looking for relationships.

Concerning the third property visibility, findings revealed that cybercrime perpetrators are patient with dealing with their victims hence creating trust which in turn get victims committed to the relationships. This finding confirms Bennett (1991) assertion that visibility influences an offending decision by allowing the offender to know that a potential target is susceptible; for an object to be targeted, an offender must know it's there.

Finally, evidence from the case points to the fact that the majority of defrauded persons tend to be people who are somewhat easily persuaded to believe the lies the scammers tell them. This attribute coupled with slow reaction from such targets make them victims of scams.

Absence of Capable Guardian

While some previous studies have considered guardianship from a digital point of view (Choi, 2008) others also perceive it as the presence and the capabilities of persons and objects to prevent crime from occurring (Tseloni, Wittebrood, Farrell, & Pease, 2004). Findings from our study is suggestive that cybercrime perpetrators explore the weaknesses in existing laws to commit online crimes. For instance, lawyers and public officials interviewed for this study were of the view that the country lacks the requisite legal and regulatory frameworks in dealing with cybercriminal offences. This finding lends credence to Boateng et al., (2011) claim that Ghana is yet to enact any law to address these forms of crime specifically. Cybercrime prosecution relies grossly on existing electronic, data protection and criminal offences acts.

This chapter further brought to the fore that offenders commit online crimes with the confidence that the police and agencies responsible for clamping down on cybercriminal activities lack the capabilities to do so i.e. they believe the authorities live in a different world with no technical knowledge of tackling the phenomenon head-on. Previous researches have emphasised on the need for law enforcement agencies to be technologically oriented in dealing with internet crimes (Boateng et al., 2011; Olayemi, 2014). Olayemi (2014) for instance posited that laws to combat cybercrimes are useless if law enforcement agencies do not have the education and training necessary even to operate a computer.

Some interesting finding from this construct was that family members of the perpetrators are aware of the acts committed by their relatives. An internet café operator disclosed that *a parent of a 14-year-old boy has been paying for the boy to chat clients... as late as after 10:00pm*. This therefore questions whether internet café operations can be regulated as a starting point toward combating cybercriminal activities in Ghana.

Regarding digital guardianship, cybercrime perpetrators find ways of dealing with anonymity both by their victims and other users of public cafés. First, they install VPNs on the computers they use at the café in order to give them the leverage of choosing their browsing locations. Secondly, they clear browsing data after using public internet cafés. They do so because users who come after them may go into browsing history and retrieve visited websites for personal gains. These findings are contrary to previous literature which have discussed digital guardianship (Bowles, 2012; Choi, 2008; Holt & Bossler, 2014; Howard, 1997; Reyns et al., 2011; Wall, 2008). These contradictions in the findings underscore the need for further studies into digital guardianship of cybercrime in the Sub-Region.

Finally, findings indicated that offenders collaborate with guardians (police, shipping agents, café operators, bankers etc.) in the commission of internet crimes. This manifest in different sections of the data presented where a lawyer alleged that *cybercriminals are friends with the police*. This was reiterated by a café operator who said *I have seen it before; a shipping company's official was tipped GH¢1,000.00 (\$200.00) for the clearance of a consignment*. This comes to confirm Aransiola and Asindemade (2011) claim that offenders' strategies include collaboration with security agents and bank officials, local and international networking.

Technology and Internet Mediation

Existing research have questioned the tenets of the routine activities theory in explaining online crimes (Eck & Clarke, 2003; Reyns, 2013). Reyns (2013) for instance suggested that critical theoretical concepts such as guardianship and target attractiveness take on new meanings in cyberspace, which necessitates adapting the concepts to online environments. Eck and Clarke (2003) also in their view noted that the theory could be expanded to accommodate actions at a distance by making one modification i.e. if the

offender and the target are on the same network. These suggestions manifested in the findings of this research in that, perpetrators of cybercriminal offences rely heavily on internet connectivity to get in touch with their victims. Again, coming from the data, case subjects ensured uninterrupted service by subscribing to private broadband service at their centre of operation. Secondly, there is a heavy reliance on technologies in committing the crimes described in the findings of this study. In romance scams for instance, computers and mobile phones play important essential roles from the search of a victim through to the termination of the relationship. It is against this backdrop that this chapter conceptualises the routine activities theory to include mediating technologies and network as represented in figure 8 below.

The Routine Activity Theory Revisited

Our conceptualisation of the theory just like Eck and Clarke (2003) is in support of the need to consider the role of networks in the commission of crimes however the influence of technology cannot be discounted (see Figure 9).

Motivated offenders consist of young people mostly between 18 and 40 who seek to exhibit extravagant lifestyles. Offenders are also motivated by certain socioeconomic factors which may include but not limited to unemployment, the desire to lift their families out of poverty, peer influence, exposure to traditional crimes among others. Others may also consist of those who are sponsored by parents to engage in internet crimes. This then leads the discussion to the absence of capable guardians. Capable guardians are made up of any obstructions to the commission of cybercrimes. These may include police, laws, legal and regulatory frameworks, parents, bystanders etc. The absence of this element serves the offender enough motivation to commit internet crimes. Further, cybercriminals thrive on the notion that the police are not adequately equipped to combat electronic crimes in the country.

In relation to suitable targets, cybercrime offenders are more attracted to rich and financially independent people. These people are mostly slow to identify scam relationships and tend to believe in what they are told by the scammers easily. Their delayed reaction and unwillingness to report cybercriminal cases also create opportunities for offenders to thrive. Victims of cybercrimes are sometimes used as transits for online shopping crimes.

Figure 9. Revised routine activity theory of cybercrime

Our primary argument for the modification of the theory comes from the fourth side; mediating technology and networks. Cybercrime arguably flourishes on the internet and as such, certain technologies such as mobile phones and computers are needed to make the cybercrime triad complete. This side of the square according to our findings must be present in order for crime to occur. For instance, offenders rely on the aforementioned technologies to commit internet crimes. Secondly, the migration from target to victim also depends upon the availability of the subject/victim online activities. This therefore demands the presence of the mediating technologies and networks. On the path of the guardian, data from the study suggested that the police needed to be equipped *technologically*; both skills and equipment. These paradoxes accentuate the need for further studies into conceptualising the routine activity theory in relation to technologies and mediating networks in cybercrime studies.

CONCLUSION

The discussion about combatting cybercrime in Ghana as indicated in the research does not seem to be fading any time soon. Even though from all indications, all stakeholders are pointing to the police to spearhead the fight against cybercrime, there requires a multidimensional consensus against cybercriminal activities.

In relation to policy, this research provides adequate findings for the Government of Ghana as well as law enforcement agencies responsible for enacting laws to expedite ongoing processes in formulating policies and laws to govern malicious use of the internet among Ghanaian youth. As evident with other ICT policies and acts such as the electronic transactions act and the data protection act, it has become necessary for civil organizations and individuals to advocate for these laws and regulations to come into being. The chapter also provides adequate findings to inform law enforcers about the modus operandi of cybercriminals. This will aid in the ongoing collaborative discussions between the ITU, Regional Development Forum (RDF) and the Government of Ghana.

With respect to practice, the police must well be resourced both technologically and with qualified personnel in the quest to combat cybercrime in Ghana. This chapter also forms a strong basis for banks, internet service providers as well as shipping and clearing agencies to collaborate with the police in the crack-down of cybercriminals. Finally, on practice, there is the need for ISPs to trace and close down cafés or deactivate mobile internet numbers which are suspected hubs of cybercriminal activities.

With regards to research, this chapter has argued for the revision of the routine activity theory to include mediating technologies and networks; hence viewing the theory from a sociotechnical lens. This research further sought for a multi-stakeholder perception of cybercrime in Ghana and revealed that there were personal or organizational gains in the nosedive of the fight against cybercrime in Ghana. This calls for a comparative research in two different countries; one with a high internet penetration rate and the other with a lower penetration rate. The research also employed a qualitative approach to analyse the multidimensional perception of the crime in Ghana. A different finding may be arrived at if the same study is conducted quantitatively.

Left-Wing Extremism From the Indian Perspective: An Econometric Interpretation

1

Sovik Mukherjee

St. Xavier's University, Kolkata, India

INTRODUCTION

Background and Motivation from the Existing Literature

To put in simple words, Left-wing terrorism (also sometimes called as Marxist–Leninist forms of revolutionary terrorism) is an action of revolt undertaken “to overthrow conservative or capitalist systems and replace them with the Marxist–Leninist or socialist societies.” (Gupta et al., 2004). However, LWE activities are not only common to capitalist regimes but even socialistic regimes have seen LWE occurring within their domestic territory against the ruling government. It has taken vivid manifestations across the world and presented diverging dynamics and relationships (Aubrey, 2004) with national governments and political economies. India is no exception.

A force centric anti-LWE policy has gained ascendancy under the current regime in New Delhi. The government has attempted to focus on increasing the capacities of the forces, undertaking proactive operations to neutralize top extremist leadership. However, like its predecessor, even the government, at present, has struggled to implement such a policy that is wracked by a range of deficiencies. The problem still persists. One of the serious problems in this regard is the lack of coordination between the police force and the CRPF. Following the April 2017 Chhattisgarh attacks, reportedly, there were issues raised as to why the police force did not cooperate with the CRPF. The UPA government had created United Command (UC) structures in four different states - Chhattisgarh, Jharkhand, Odisha and West Bengal - to establish coordination between the various forces who take part in these anti-LWE operations. It was later revealed that the UC structures did not meet every six months, as per the norms and guidelines laid down, but as per the convenience of the concerned authorities and mostly, after a major attack. It is to be noted that a meeting of the UC in Chhattisgarh took place in May 2017, after a gap of 15 months and was convened only after two major attacks by the extremists in March and April 2017 (Routray, 2017).

From the security force point of view, a popular theory has been around for a while prescribing a solution to the LWE problem. It says the CPI-Maoist can be defeated only by sustained deep penetrating operations into the core extremist stronghold areas. While this can certainly provide a solution to the military nuisance of the CPI-Maoist, somehow most state administrations have managed to elicit only a partial involvement of the civil administration whose role in these areas assumes critical importance. States over the years have indeed taken gradual steps to increase the writ of the state into the hitherto LWE dominated areas (Suneja, 2018). As Routray (2017) points out, in Chhattisgarh, there have been new security posts coming up in places like, Kistaram-Golapalli (Sukma) and Bhadrakali (Bijapur) and the Bastar range now has 14 helipads equipped for night landing of choppers used mostly for logistical duties. It is a matter of great pride that such moves have indeed been successful despite extremists at-

DOI: 10.4018/978-1-5225-9715-5.ch006

tempts to mount repeated attacks on the security forces setting up such camps and also public relations campaigns urging tribals to undertake ‘*Police Camp Bhagao Andolan*’ (movement to chase away police camps). Also, other measures initiated by New Delhi for the LWE affected areas include road connectivity projects, mobile connectivity through installation of mobile towers, making education and skill education accessible by initiatives like Rashtriya Madhyamik Shiksha Abhiyan (RMSA), Sarva Shiksha Abhiyan (SSA), establishing Kendriya Vidyalaya (KVs) in the affected districts, opening up of banks, ATMs, etc. to be able to make inroads into the extremist dominated areas. Given such initiatives, the contribution of the paper lies in econometrically estimating the extent to which these developmental factors affect the occurrence of LWE activities.

Thus, Left Wing extremism (henceforth, referred to as LWE)¹ has emerged as one of the major security challenges that India faces. This cannot be a mere manifestation of the prolonged state-building process that the states within the region have been undergoing but rather a movement towards dismantling the existing disproportionate socio-economic and political structures established for catering to the interests of the upper strata of the society. The relative success that these groups have been able to achieve varies from place to place and group to group. Despite shrill assessments across the board and an enveloping sense of apprehension promoted by polarizing politics, the past year has been astonishingly peaceful in India in terms of terrorist and insurgent violence. Total terrorism/insurgency related fatalities across India at 411 (see Table 1), are at a dramatic low - certainly, the lowest since 1994. Indeed, since 2012, total fatalities across the country have remained below the ‘high intensity conflict’ threshold of a thousand fatalities per year. It is useful to recall that fatalities remained above 2,000 for 18 of these 22 years; out of which they were above 3,000 for 11 years; above 4,000 for five years; and just over 5,000 only in 2001. The cumulative totals of the multiple insurgencies in India’s **troubled Northeast**, similarly, remained above the ‘high intensity’ threshold in 2007 and 2008, but have declined enormously since then. As projected, the dramatic contraction of Left Wing Extremism (LWE) – in terms of geographical areas of influence and violence has primarily been the result of successful intelligence-based operations launched by the Security Forces (SFs) over the past years, which have helped neutralize top cadres among the rebels. According to the SATP database, between 2010 and 2016, at least 677 leadership elements of the Maoists have been neutralized (84 killed, 391 arrested and 202 surrendered). To name a few of the initiatives, according to the Union Ministry of Home Affairs (UMHA) data, the total number of LWE cadres arrested between 2010 and 2015 stands at 11,608. At least 633 LWE cadres surrendered

Table 1. Trend in deaths on account of LWE activities in the last 5 years

Year	Civilians	Security Forces	Terrorists/Insurgents/Extremists	Total
2020 (E)	101.8	62.8	275.6	437.8
2019 (E)	104.1	65.5	249.8	417.8
2018	106.0	75.0	230.0	411.0
2017	109.0	76.0	150.0	335.0
2016	123.0	61.0	251.0	435.0

*: Total is only from the actual figures i.e. from 2014-2018

over the same period. As SFs establish dominance the erstwhile areas of LWE dominance, efforts at the level of civil consolidation have also increased. UMHA has now claimed the implementation of the Fortified Police Stations (PSs) scheme for construction/strengthening of 400 Police Stations in 10 LWE affected States at INR two million per Police Station on a funding pattern of 80 per cent (Central share): 20 per cent (State share) basis. Also, the Ministry of Road Transport and Highways (MoRTH), under the Road Requirement Plan-I (RRP-I), across eight states of India, has constructed 3,904 kilometers of roads (till 31st of January, 2016). However, in the Indian context, the empirical literature remains under-developed (see Mazumdar, 2013; Pillai, 2010; Basu, 2011; among others). The author pitches herein with an econometric model to estimate the impact of socio-economic parameters, poverty and inequality on LWE related deaths.

This paper makes an attempt to contextualize the nature and spread of LWE and the threat it poses to the Indian state. Are the states vulnerable to such attacks experience an inertia effect from the past LWE activities? The rest of the paper has been organized as follows. The current positions of the severely affected states in India have been highlighted and following this, the empirical model has been estimated. The paper finally ends with consequential discussions and future research possibilities thereof.

Objectives

It is often a fact that it is this highly disproportionate appropriation of resources across the different sections of the society that is actually the cause of social deprivation which in turn creates the breeding ground for social tension. Furthermore, the causes of social unsustainability are often centred on religion, caste and other divisive factors which may tend to polarize the people. The interaction of the host of such complex factors may thus create problems of social sustainability which would also be having adverse feedback effect on productivity of resources and economic growth.

Figure 1. The extent of spread of Left-Wing Extremist Activities_recent in 2018

Source: South Asia Terrorism Portal;

Note: Based on 2017 data

Against this background, the paper tries to geographically locate the pockets where such forms of crime are the most prevalent and do a trend analysis for these states over a period of five years. In addition to this, the paper models Left Wing extremist activities across twelve severely affected states² in India for a period of nine years from 2008-2017 in a Generalized Method of Moments (GMM) set-up to take care of the endogeneity problem which are quite likely to arise in case of such analysis. In conclusion, the results highlight that while economic growth has a definite positive role in abating such violent forms of left-wing extremist crime, the development strategy should give high priority to literacy, internal security and human development.

CURRENT POSITION OF LEFT WING EXTREMISM ACROSS INDIAN STATES

Extremist activities constitute a source of violence and crime across selected states in India (refer to Figure 1 for the geographical details) in certain regions like Kashmir, certain parts of North Eastern states, as well as in states of Eastern, Central and Southern India like Jharkhand, Bihar, Chhattisgarh, Madhya Pradesh, Odisha, West Bengal, etc.. The form of violence has been mostly of insurgency, terror attacks by poor people mobilized by the political activists who are driven by their political and economic ideology and agenda. The famous terror attacks of Kashmir Valley are mostly driven by political factors and issues of dispute between the Indian states on the one hand and the Pakistani state, Pakistan supported terror groups or the local Kashmiri political-economic entities on the other. The insurgency problem of the Northeast is again attributable to complex regional, ethnic and political issues along with the long neglect of development in the region. However, the motivation of this paper is particularly on the violent terrorist activities of insurgency in certain parts of Eastern, Central and Southern states being driven by mainly Left-Wing Extremist (Maoists or Naxalite or Extremist) groups and not general terrorist attacks *per se*. The pattern of such incidents across the different districts of the states under consideration is highlighted in Table 2 while the projection for India on the whole has been given in Table 1.

As on December 2017, the number of districts affected across 09 states stands at 105. The districts affected by left wing extremism stood at 106 in 10 states as on February 2016.

The journey from when LWE became active in the 1960s till date has been a threatening experience for peace and security. In the 1960s, when it began, LWE concentrations were mostly in the state of West Bengal, areas like Naxalbari, Khoribari, etc.. With the passage of time, basic motivational issues for such forms of extremism like poverty, inequality, social deprivation and discontent among the masses have assumed center stage and now, India's celebrated 'Red Corridor' spreads across ten states as described in Table 3. Their violent agenda and mass outcry against the state, rejecting parliamentary politics has intensified the internal security threat in India, at present — the intensity being higher in states like, Bihar, Jharkhand, West Bengal and Chhattisgarh. If one observes Table 3, this stretch of the 'Red Corridor' starts from India's border with Nepal to the absolute northernmost fringes of Tamil Nadu, including the coastal parts of states like West Bengal and Odisha.

METHODOLOGY

In the existing literature (see for example, Kelly, 2000; Osgood, 2000 among others) the number of occurrence of any type of left-wing extremist activity is a discrete random variable and its average rate of occurrence (λ) is fixed for a defined period. Again, the chance of occurrence of the event at any point of

Note: These data are not deaths due to terrorist activities but deaths due to LWE activities. One should also note that we have excluded Jammu and Kashmir because for the state of Jammu and Kashmir it is very difficult to differentiate out the deaths caused to general terrorist activities from terrorist activities on account of LWE.

Table 3. The districts affected across the states in India

State	Number of Districts in State	Number of Districts Affected	Districts Affected
Jharkhand	24	18	Hazaribagh, Lohardaga, Palamu, Chatra, Garhwa, Ranchi, Gumla, Simdega, Latehar, Giridih, Koderma, Bokaro, Dhanbad, East Singhbhum, West Singhbhum, Saraikela Kharsawan, Khunti, Ramgarh

Source: Press Information Bureau Release, Government of India (2018)

time is independent of when last the event had occurred. It is generally assumed the probability density function of the number of occurrences of such form of crime in a large number of trial experiments of the crime event, is a Poisson density function: i.e.,

$$P(x = k) = \frac{e^{-\lambda} \lambda^k}{k!}$$

Its mean and variance would both be λ .

But, in this model, the author relaxes the assumption of the chance of occurrence of the event at any point of time being independent of when last the event had occurred and introduces an inertia effect. Extending the model proposed by Sengupta and Mukherjee (2018), for any of the individual crime, its average or expected number of occurrence per period is a function of per capita GSDP growth rate, state literacy rate (per cent), size of the police personnel per 1000 units of population, road density of the state per square km. unit, share of minority population (per cent), share of SC/ST population. The double log linear relationship between LWE related deaths and the above mentioned explanatory variables is given below.

We have normalized the measures of some of the variables and/or changed the units of measures in the interest of better presentation or interpretability of the results. For example, we normalize all the relevant variables in per capita terms, or, say, variables like police force size in terms of number per 1000 of population, etc. Again, given the nature of the dependent and independent variables considered, the multiple regression models would often involve endogeneity problems due to the existence of correlation between some of the explanatory variables on the error term of the dependent variable. In view of this we run the Generalized Method of Moments (GMM) to estimate most of the relationships by using the lagged values of such endogenous variables.

If z_i be the crime variable for the i^{th} state, x_j be the j^{th} inequality/poverty variable, y_k be the k^{th} other socio-economic co-variables; influencing the crime variable, the proposed models are the following double log linear ones:

$$\log z_i = \alpha_i + \sum_j \beta_{ij} \log x_j + \sum_k \gamma_{ik} \log y_k + \varepsilon \quad (1)$$

i = Left Wing Extremism related deaths for state i ; j = Gini coefficient (inequality) index, poverty head-count ratio.

k = per capita GSDP growth rate, state literacy rate (per cent), size of the police personnel per 1000 units of population, road density of the state per square km, share of minority population (per cent), share of SC/ST population.

The advantage of using such GMM estimators gets clearly explained when the properties of the estimator does not get distorted when N is small (see Blundell & Bond, 1998; Blundell & Bond, 2000). Moreover, earlier, distribution specific estimators used Monte Carlo simulations where it was not possible to exploit the full set of moment conditions based on instruments when N was small contrary to what happens in this context.

Coming to the estimation procedure, this paper makes use of Generalized Method of Moments (GMM) approach which is superior to Ordinary Least Squares (OLS) and Maximum Likelihood Estimation (MLE) as both in case of OLS and MLE the underlying distribution has to be normal to achieve the desired properties. Moreover, econometric estimation of growth models is usually undermined by the omitted variable and/or the endogeneity problem. There can be an issue of reverse causality which may create biased estimates otherwise. In such a situation OLS fails. The 2SLS estimator, on the other hand, while preferred, is inefficient if there is heteroskedasticity in the data. However, GMM satisfies the properties of efficiency even in case of heteroskedasticity (Siddiquia & Ahmed, 2013). Moreover, system GMM

is a computationally convenient method for estimating a non-linear model without completely knowing the specificity of the probability distribution of data. Here, to take care of the inertia effect, the paper introduces Arellano-Bond estimator. Before starting off, a short technical note needs to be understood first. An unrestricted number of lags of the explanatory variables will introduce a massive number of instruments and eventually, result in a loss of efficiency so following Cameron and Trivedi (2005), there can be a maximum of 4 lags.

However, coming to the decision of considering four lags has been determined by the test of over-identifying restrictions i.e. Hansen's test of over identifying restrictions. The results of which are reported in the next section and are consistent with the statements made by Cameron and Trivedi (2005). Hansen's (1982) J test corrects Sargan's test of over identifying restrictions in the presence of heteroskedasticity. The statistical confirmation of the null hypothesis means the instruments fit the data well but the acceptance of the alternative hypothesis rejects the validity of the instruments (refer to Sargan (1958); Hansen (1982)). The set of assumptions are, $E(\varepsilon_{it})=0$ and $E(x_{it}\varepsilon_{it})=0 \forall t \neq s$.

Coming to the general definition of the Arellano-Bond estimator,

$$\hat{\beta} = \left[\left(\sum_{i=1}^N X_i' Z_i \right) W_N \left(\sum_{i=1}^N Z_i' X_i \right) \right]^{-1} \left(\sum_{i=1}^N X_i' Z_i \right) W_N \left(\sum_{i=1}^N Z_i' y_i \right)$$

and $W_N = S^{-1}$ where,

$$S = \frac{1}{N} \sum_{i=1}^N Z_i' \varepsilon_i \varepsilon_i' Z_i, \text{ where, } \varepsilon : NT \times 1$$

i.e. a set of 8 regressors over 15 time periods.

We have estimated these models with panel data formed out of basic data on violence due to Left Wing Extremism, road density and other developmental factors as obtained from the National Crime Records Bureau of Statistics, road density data per sq km from Road Research Wing of the Ministry of Transport and Highways and other developmental parameters compiled from the Planning Commission and CSO database (see Table 4). It needs to be mentioned that while z_i 's are scalars, the x_i and y_i 's together make it a 1×9 vector (including the constant intercept term) comprising of the regressor variables and their difference levels as given in the specified model equation. When the number of columns in the z_i vector becomes very large, computational considerations may not require the comprehensive use of all possible instruments (see for details Alvarez & Arellano, 1998). In case of a given cross-sectional sample of size N, the use of too many instruments may result in overfitting biases. Given this consideration and following the result of Hansen (1982) test the author sticks to 2 lags and has ignored the least informative instruments.

Primarily, the state response to such LWE activities has suffered due to perceptual differences among the states as well as lack of a unified outlook among the regimes in power. Lack of inter-state coordination and lack coordination between the police and the para-military remains a problem. In some of the tribal areas across states (see Table 3), provision of basic public good services, in terms of education, road connectivity, etc. is lacking which has led to the emergence of Naxalite cadres. Combining development approach with security force operations, emphasis on infrastructural development for road connectivity for human mobility and internal security for peace building should be accorded high priority. Nevertheless, growth with job creation is a necessary condition for a crime free society but not

Table 4. The variable description and the data source

Variable Name/Specifications	Explanation	Data Source
LWE deaths	Number of incidents of violence causing death due to Left Wing Extremism	Crime Records Bureau of Statistics and South Asia Terrorism Portal
GINI Coefficient	To capture the relative dimensions of social tension	Planning Commission Databook, December 2014 and CSO Database
Poverty head count ratio	To capture the absolute dimensions of social tension	Planning Commission Databook, December 2014 and CSO Database
Road density per sq km.	Socio-economic developmental factor	Road Research Wing of the Ministry of Transport and Highways, Government of India

sufficient. The sufficiency condition requires appropriate growth policy targeting the proper distribution of the growth benefit, infrastructure development and education and literacy. Education, literacy and per capita GSDP growth are in fact fundamental to abate Left Wing Extremism in India. Law and order solution is necessary but not again sufficient in this context of LWE. The social policies of development should take care of problems of divisiveness due to religion or caste factors in society as riots are found to be sensitive to share of minority or that of SC/ST population and ensure social cohesiveness in our development process. Thus, justifying the choice of variables taken up in this regard.

RESULTS

In order to examine the significance of the impact of the above mentioned explanatory factors on the incidences of violence causing death due to Left Wing Extremism, the author sets up the following econometric models,

Dependent variable is – Number of incidents of violence causing death due to Left Wing Extremism;

Independent variables – Model in Table 6 has Inequality (GINI coefficient) while Model in Table 7 has Poverty (Poverty Head Count Ratio). The other explanatory variables remain the same under both the models which include — road density, literacy rate, growth rate of per capita state gross domestic product, size of police personnel per 1000 population and the vote share of extreme political parties that had contested any form of election in that state concerned in that year.

It may further be noted that the regions (districts) which are affected by poverty and inequality in income distribution also suffer from low level and lack of infrastructural amenities, particularly road connectivity. The latter facilitates terror attacks in the form of insurgency. The geographic maps of for-

est cover, distribution of poverty and that of low level of road density overlap each other in such region. However, the incidences of such Left Wing Extremism are also contingent on the basics of determinants of human development, like education and economic growth which are likely to reduce such crime rates. The development of internal security infrastructure (say size of police personnel) in the state would also tend to abate the incidences of such insurgency related crime committed by the Left Wing extremists.

The basic objective of going for this dynamic panel estimation is to see whether incidences of LWE from the past year consequentially leave behind any kind of inertia effect on the current year LWE activities. Also, if any possibility of endogeneity exists then it would automatically get taken care of through the Arellano-Bond test (Das & Mukherjee, 2018). One needs to clearly understand as to why for small T and large N Arellano-Bond estimator is the preferred estimator. In large-T panels, a shock to the country's fixed effect will make the error term component to decline over time and also the correlation of the lagged dependent variable with the error term will become insignificant (see Roodman, 2009). For combinations of small T and large N panels, this is not necessarily the case and the need for using the Arellano-Bond estimator. The results have been reported in Table 6 and 7.

According to Das and Mukherjee (2018), sometimes the lagged values of the regressors are poor instruments for the first-differenced regressors of equation 1. The Arellano-Bond estimator at the first difference level actually makes these explanatory variables get instrumented with their own lagged values. Before moving on to the discussion of the Hansen test the discussion regarding the two step working mechanism of the GMM estimator, as Das and Mukherjee (2018) have explained, — “There is a two step Generalized Method of Moments method to getting the correct number of lags. First, as an econometric modeller, not only modeling the var-cov matrix under homoskedasticity, but also incorporating the obvious serial correlation in the first difference of the error term components. Next step is to use the residuals from the first step to optimize the weighting matrix which will be consequently used to weight the second stage of the regression.” The results in Table 5 suggest that there is no autocorrelation for higher order lagged values.

The presence of ‘no serial correlation in the first-differenced errors’ as shown in Table 5, at an order higher than 1 means that the moment conditions used by the Arellano-Bond estimator are very much valid. Consequently, after checking with 3 period lagged values as instruments which did not turn out to be significant, the author has used ‘2 period lagged values’ as instruments in this model. Under heteroskedastic data, Eviews 7 package reports the J statistic as distribution of the Sargan test is not known when one deals with heteroskedastic data (Das & Mukherjee, 2018). The model has been estimated based on the Anderson-Hsiao estimator derived from the first-differenced equation, in doing so, instrumenting the lagged dependent variable with the ‘2-time period lagged level values’ of it (Anderson & Hsiao, 1982).

The results in Table 6 and 7, clearly shows that inequality position of the states in India severely affected with LWE activities has a greater intensity in affecting the number of LWE deaths when compared with the poverty head-count ratio. In all the versions of the model considered here, the author makes use of double logarithm Generalized Method of Moments regression method for estimation. Each of the two models have been estimated at the level values of the dependent and independent log variables as well

as at their first differences. The inequality or poverty related measures as independent variables have a significant impact on the number of deaths due to such violence. Also, the infrastructural variables like, road and internal security infrastructure in terms of road density per sq km. and number of police personnel per 1000 population tend to reduce such impact on the dependent variable of violent incidents of LWE as expected while the human development factors like state level of literacy have also a significant moderating effect on such events through its impact on overall level of development of the state. Interestingly, the share of minority population has turned out to be a significant factor while the share of SC/ST population remains insignificant. The variables representing the share of minority population or of SC/ST population represents the policy of promoting social cohesion and those of protection of minority as well as dalits are important for peace and cohesion. Moving on, the dynamic panel data model objectively points out to the fact that states having a history of being subjected to LWE terror attacks are vulnerable to such activities. Hence, the inertia effect of terrorism LWE continues to live on i.e. death due to LWE in the past year is directly influencing LWE activities in the in the current year.

However we observe that the results at the first difference level show the impact of the parameter on inequality or poverty as insignificant possibly due to a small sample problem on account of data limitations. We have therefore to use the results of Tables 6 and 7 based on level values of the variates for the policy and other analytic purpose.

CONCLUDING REMARKS AND FUTURE RESEARCH AREAS

The ‘National Policy and Action Plan (NPAP)’ since 2015 launched by the Union Ministry of Home Affairs (MHA) pushes for zero tolerance towards violence coupled with massive efforts put in developmental activities so as to streamline such benefits to the poor and the vulnerable sections in the affected areas. This policy covers 106 districts in 10 states, as already pointed out, which are severely affected by Left Wing Extremism affected. As per NPAP, these districts are covered under the “Security Related Expenditure Scheme (SRE) of the MHA for the purpose of reimbursement of security related expenditure like transportation, communication, hiring of vehicles, stipend for surrendered Maoists, temporary infrastructure for forces etc. to the states”. The reports indicate a substantial decline of around 34 per cent in the number of deaths related to LWE across 58 districts between 2013 and 2017. As a pre-emptive move, the MHA has put tribal areas at the intersection of the states of Kerala, Karnataka and Tamil Nadu under SRE districts. The effectiveness of NPAP in the recent years has brought the list of ‘Most Affected Districts’ to 30, down from 36 — an achievement of some sorts. The policy implications of these results as presented in Table 6 and 7 point out clearly that both inequality and poverty parameters have significant impact with high positive elasticity on such LWE activities. The inequality measure has however relatively higher impact in terms of its absolute elasticity value when compared with the poverty head count ratio. All the other developmental variables including, security related infrastructural connectivity are found to reduce the violent activities by LWE. However, a few points should be noted here:

1. The relative disparity in income and asset distribution, and, not just poverty, has a massive role and significance in accelerating violence of the kind being discussed.
2. Educational attainment and literacy are two of the most important developmental instruments in abating such acts of violence driven by political economic factors.

3. Growth has a special place in the developmental policy of the states concerned. The magnitude of the partial elasticity coefficient of growth, in essence, has a role in eradicating absolute deprivation or poverty but also reducing the inequality among the poor (refer to Table 6 and 7).
4. Last, but not the least, the inertia effect persists from the previous period. The empirical exercise advocates that states having a record of LWE activities will experience such activities, even in the current period. Lower growth in an area having a higher vote share of extreme political parties is an important determinant of political radicalism: a lower growth rate increases the support for extreme political platforms — very true in the Indian context.

The present analysis may be extended in several dimensions. This empirical model has been proposed keeping in mind the Indian context but one can extend it to other developing countries having a history of LWE occurrences. Moreover, India is the largest democracy in the world, so it would be interesting to explore these results for countries having little or almost no experience of democracy. Over a period of time, this model can be effectively used for predicting to what extent the factors considered here are being influenced by the NPAP. Subject to data availability, the scope of further research would be incomplete without tracking down major episodes of natural disasters and calamities, financial and banking crisis, political referendums, etc. and how the results derived in this model change in presence of such factors in a cross-country set-up.

KEY TERMS AND DEFINITIONS

Economic Growth: It can be defined as the increase in the capability of an economy to produce goods and services from one period to another. It can be measured either in nominal terms or in inflation adjusted real terms. Typically, GDP or GNP is taken as a measure of economic growth. In notational terms, GDP growth rate, g_t , $g_t = \frac{GDP_t - GDP_{t-1}}{GDP_{t-1}} \times 100$ where, t indicates the particular time point.

Generalized Method of Moments (GMM Estimation): It is a common method for estimation of the parameters in statistical models. Usually it is applied in the context of semiparametric models, where the parameter of interest is finite-dimensional, whereas the full shape of the data's distribution function may not be known, and therefore maximum likelihood estimation is not applicable. Using the moment conditions, the true parameter values are estimated. The GMM method then minimizes a certain norm of the sample averages of the moment conditions. It is applied in case when there can be a chance of endogeneity problem.

Gini Coefficient: In economics, the Gini coefficient sometimes called Gini index, or Gini ratio, is a measure of statistical dispersion intended to represent the income or wealth distribution of a nation's residents, and is the most commonly used measurement of inequality.

Maoists: Maoists, also known as Naxalites or Naxals, are the group of people who believe in the political theory derived from the teachings of the Chinese political leader Mao Zedong. It is a doctrine to capture State power through a combination of armed insurgency, mass mobilization and strategic alliances. Also, these Maoists use insurgency doctrine based on use of propaganda and disinformation against State institutions. Herein, the author has used Maoists, left-wing extremists, and Naxalites interchangeably.

Monte Carlo Simulations: Monte Carlo simulation is a mathematical technique that generates random variables for modeling risk or uncertainty of a certain system. The random variables or inputs are modelled on the basis of probability distributions such as normal, log normal, etc. Different iterations or simulations are run for generating paths and the outcome is arrived at by using suitable numerical computations.

Panel Data: Also called longitudinal data, represents cross-sectional time series data i.e. data on multi-dimensional cross-sections (comprising of individuals, firms and countries) over a period of time.

Police Force: A body of trained officers entrusted by a government with maintenance of public peace, law and order, enforcement of laws, and prevention and detection of crime.

Poverty Head Count Ratio: The poverty head count ratio (PHCR) is the proportion of a population that exists, or lives, below the poverty line.

ENDNOTES

- ¹ The terms “Naxalites”, “Maoists”, and “Left Wing Extremists” have been used inter-changeably.
- ² The states are Jharkhand, Bihar, Chhattisgarh, Madhya Pradesh, Odisha, West Bengal, Andhra Pradesh, Telengana, Assam, Nagaland, Kerala and Maharashtra. We have not considered any North Eastern state because of lack of availability of data, except for Assam and Nagaland.

Transnational Cybercrime: The Dark Web

Barbara Jane Holland

Brooklyn Public Library, USA

INTRODUCTION

The world and human behavior have changed so quickly through the use of technology.

China and India have the largest population of internet users though only 55 percent and 34 percent have total access (Internet live stats 2016). The United States, Brazil, and Japan come next.

The proliferation of technology has clearly led to changes in how individuals engage with the world around them. Today people shop and communicate in digital format.

Most people born in the mid-eighties have never lived without a computer. The endless development of human behavior has created unparalleled opportunities for crime and misuse.

Over the past thirty years, there has been a substantial increase in the use of technology by street criminals and new forms of crime that did not previously exist.

Technology is at the core of information security. It can enable crime, and but also prevent it.

Every country has its own police agency that enforces its own laws. The growth of global transportation systems, international trade, computerized financial transactions, and worldwide availability, of information through the internet have facilitated the expansion of the international economy. These factors simultaneously provided the basis for transnational crime. There is a distinction between profit-seeking transnational crime and international crimes. Which are acts of terrorism, genocide, human rights abuses and other crimes that violate international law (Albanese 2011). Transnational crimes, by contrast, include theft, fraud, counterfeiting, smuggling and other violations of individual countries' criminal laws that involve trans-border activities.

BACKGROUND

Cybercrime involves the use of computers and the internet to commit acts against people, property, public order or morality (de Villiers 2011). Some may occupy a computer to steal funds, information or resources. These thefts can be aimed at stealing money, company trade secrets, chemical formulas, and other information that could be valuable to a competing business. Others may commit destructive acts by releasing a malicious virus or worm to harm a computer system.

Cybercrime is an evolving form of **transnational** crime. The complex nature of the crime as one that takes place in the border-less realm of cyberspace is compounded by the increasing involvement of organized crime groups.

Table 1. World wide web

Surface Web Google, Bing Facebook LinkedIn, eBay, Amazon Illicit online pharmacies Anonymous forums	Deep Web Medical Records Legal documents scientific Reports Academic documents Government documents	Dark Web Mirrored Websites Private Communication Illicit Activity
---	---	---

Transnational Cybercrime can be grouped into three categories. (Albanese, 2011).

The First Category: Provision of illicit goods such as drug trafficking, moving stolen automobiles and artwork, from one country to another for sales, is difficult to trace back to its original owner. (Alderman, 2012). Also included is the transportation and sale of counterfeit goods such as prescription drugs, medication and designer clothing.

The Second Category: Provision of illegal services, includes human trafficking, with the transportation of sex workers or undocumented immigrants illegally into the country(Shamir 2012). Also included are fraudulent investments and child pornography.

The Third Category: Infiltration of business or government. (Albanese 2011). This category includes the widely publicized conclusion by American Intelligence agencies that Russians under the direction of the Russian Government, sought to affect elections in the United States by hacking into American computers and selecting revealing information that would help or hurt certain political candidates. According to the United Nations, the annual profits from Transnational organized crime amounts to 870 billion annually with drug trafficking producing the largest segment of that amount.

Law enforcement official faces huge challenges in combating transnational crime.

THE SURFACE WEB

The magnitude of the web is growing. According to one estimate, there were 334.6 million internet top-level domain names registered globally during the second quarter of 2016. This is a 12.9% increase from the number of domain names registered during the same period in 2015. As of February 2017, there were estimated to be more than 1.154 billion websites.

The Deep Web comprises any content on the web that is not indexed for search engines and that is accessed by password or encryption, or through gateway software. This includes content such as medical records, legal documents, financial records, and government resources. Because this content cannot be searched and indexed, no one knows exactly how large the deep web is, but many estimates place it at 400 to 500 times larger than the surface web.

Deep Web Search Engine

The Torch is one of the most well-known and well-loved deep web search engines there is, and it's also one of the largest. Their index covers more than a million deep web page results. It makes for a great multi-purpose search engine whatever you're looking for.

Popular Deep Web Destinations

- **TorShops:** Start your own deep web store!
- Onion URL Repository
- The WWW Virtual Library
- Tor Links – A list of .onion addresses.
- Facebook
- Hidden Answers
- Dream market
- Sci Hub

THE DARK WEB

The **dark web** is a subset of the **deep web**, which is not indexed by traditional search engines within the Deep Web. The Dark Web is also growing as new tools make it easier to navigate. Individuals may access the Dark Web assuming the little risk of detection, and use this arena for a variety of legal and illegal activities. It is unclear, however, how much of the Deep Web is taken up by Dark Web content and how much of the Dark Web is used for legal or illegal activities

The Dark Web can be reached through decentralized, anonymized nodes on a number of networks including Tor (short for The Onion Router) or I2P (Invisible Internet Project) Tor, which was initially released as the Onion Routing project in 2002. It was originally created by the U.S. Naval Research Laboratory as a tool for anonymously communicating online.

The Dark Web and Tor

Tor “refers both to the software that you install on your computer to run Tor and the network of computers that manages Tor connections. Tor’s users can connect to a website through a series of virtual tunnels rather than making a direct connection, thus allowing both organizations and individuals to share information over public networks without compromising their privacy. Users route their web traffic through other users’ computers such that the traffic cannot be traced to the original use or essentially establishes layers (like layers of an onion) and routes traffic through those layers to conceal users’ identities. To get from layer to layer, Tor has established “relays” on computers around the world through which information passes. Information is encrypted between relays, and all Tor traffic passes through at least three relays before it reaches its destination. The final relay is called the “exit relay,” and the IP address of this relay is viewed as the source of the Tor traffic. When using Tor software, users’ IP addresses remain hidden. It appears that the connection to any given website is stemming from the IP Address of a Tor exit relay, which can be anywhere in the world. Although data on the magnitude of the Deep Web and Dark Web and how they relate to the Surface Web is not clear, data on Tor users do exist. According to metrics from the Tor Project, the mean number of daily Tor users in the United States across the first two months of 2017 was 353,753—or 19.2% of total mean daily Tor users. The United States has the largest number of mean daily Tor users, followed by Russia (11.9%), Germany (9.9%), and the United Arab Emirates (9.2%)

Timing Analysis

Utilizing timing analysis, the anonymity of TORs can be broken. One of the reasons typical Internet connections are not considered anonymous is the ability of Internet service providers to trace and log connections between computers. For example, when a person accesses a certain website, the data itself may be secured through a connection like HTTPS such that your password, emails, or other content are not visible to an outside party, but there is a record of the connection itself, what time it occurred, and the amount of data transferred.

1

1

Traffic Analysis

Traffic Analysis can intercept and examine messages in order to deduce information from patterns in communication. This can be performed with messages that are encrypted.

Deanonymization can occur when using end-to-end timing attackers. An adversary monitoring network traffic sent to the initial relay node, as well as traffic sent to the final relay node, can make use of statistical analysis to identify the circuit they belong to. The user's IP address, as well as the destination IP of the observed traffic, can be sniffed by the adversary, who can easily track the clickstream of a user via correlation attacks. The adversary does not need to control the entry and exit nodes within a Tor circuit to be able to correlate network traffic streams observed traveling across these relay nodes. The adversary only needs to be capable of observing the traffic.

Purchasing Drugs and Narcotics Online

The sale of illicit drugs and narcotics has also moved online. The primary resources used by sellers and buyers are on forums operating on the Dark Web which can only be accessed by using specialized encryption software and browser protocols. Individuals can only access these forums using the Onion router or Tor service which is a free proxy and encryption protocol that hides the IP address and location of the users (Barrett, Ferris, and Winstock, 2014; Dolliver, 2015). Moreover, these sites cannot be indexed by Google or other search engines. As a result, this limits the ability of law enforcement agencies to eliminate illicit content because the hosting source cannot be identified through traditional means (Dolliver 2015; Estes 2014).

Silk Road was one of the first Tor-based narcotics markets to gain prominence. The market gained attention from researchers and popular media. Transactions were paid through an anonymous electronic currency called Bitcoins. Law enforcement agencies in The United States and Australia conducted sting operations against the buyers.

Since the opening of Silk Road in 2011, there were over a million transactions worth an estimated 1.2 billion in revenue. An FBI investigation using the handle **Dread Pirate Roberts** led to the arrest of Ross William Ulbricht in San Francisco California October 2, 2013.

Some sites effectively "hidden", have not been indexed by a search engine and can only be accessed if you know the address of the site. Special markets also operate within the dark web called, "darknet markets", which mainly sell illegal products like drugs and firearms, paid for in the cryptocurrency Bitcoin.

Another hidden site called **Assassination Market**, created by Kuwabatake Sanjuro allows users to crowdfund murders through donations of Bitcoin, the anonymous digital currency. The site, which has been up less than a year, is only accessible through the Tor network, currently, lists a total of six bounties, all of which target various government officials. As a result of the dark web's almost total anonymity, it has been the place of choice for groups wanting to stay hidden online from governments and law enforcement agencies. Whistleblowers are known to use the dark web to communicate with journalists, but more frequently it has been used by pedophile groups, terrorists and criminals to keep their dealings secret.

A recent study by Carnegie Mellon researchers Kyle Soska and Nicolas Christin has calculated that drug sales on the darknet total US\$100 million a year. Most, if not all, was paid for in Bitcoin.

Figure 7. Blockchain

BITCOIN AND BLOCKCHAIN ON THE DARK WEB

When Bitcoin surfaced, it promised complete anonymity and this caused the global community to embrace it with open arms. However, the nature of blockchain is such that tech-savvy individuals could become privy to the addresses of people making huge transactions on the network. Currently, Cryptocurrencies

like Litecoin and Monero are currently making waves in the market and this is due to the shift from a Bitcoin economy to an altcoin one. These altcoins are more favorable because they process transactions faster and with a certain level of reliability, they also uphold the concept of anonymity better. Their relatively low transaction fees and value also makes it better. The blockchain is an integral part of the dark web and cryptocurrency has been instrumental to its growth.

Sellers and Aliases in the Marketplace

Silk Road became the central dark web marketplace in 2011. Before it was seized by the FBI in 2013; Silk Road 2.0 emerged as the dominating marketplace before being shut down in 2014 in an international effort dubbed Operation Onymous. Evolution then became the leading marketplace before engaging in an exit scam in and was then replaced by Agora, which halted operations as a result of attacks to de-anonymize its server locations. The rise and eventual capture by law enforcement of Alpha Bay and Hans paved the way for the current leader, Dream Market.

November 2014, another San Francisco man by the name of Blake Benthall was arrested and charged with being "Defcon," the Silk Road 2.0 administrator.

Unlike the surface web, a primary function of these dark web marketplaces is to serve as escrow agents between the buyer and the seller, for which the marketplace collects a small fee. Escrow helps to prevent seller and preserves the anonymity of purchases because marketplaces typically tumble the cryptocurrency in the process. Most marketplaces use a technology called multi-signature transactions ("multisig") that require the approval or "signature" of multiple parties in a transaction before payment is released from escrow. 2-of-2 multisig requires both the buyer and seller to sign off before money is released. An increasingly popular option is 2-of-3 multisig, in which two of three parties engaged in a transaction (buyer, seller, and escrow agent) must sign off to release funds.

Following the Silk Road blueprint, modern online anonymous markets run as Tor hidden services, which gives participants (marketplace operators and participants such as buyers and sellers) communication anonymity. Online currencies are used as payment systems (e.g., Bitcoins) to make it possible to exchange money electronically without the immediate traceability that conventional payment systems (wire transfers, or credit card payments) provide.

The common point between all these marketplaces is that they actually are not themselves selling contraband. Instead, they are risk management platforms for participants in (mostly illegal) transactions. The risk is mitigated on several levels. First, by abolishing physical interactions between transacting parties. These marketplaces claim to reduce (or indeed, eliminate) the potential for physical violence during the transaction. Second, by providing superior anonymity guarantying online anonymous marketplaces and participants shield from law enforcement intervention. Third, online anonymous marketplaces provide an escrow system to prevent financial risk. These systems are very similar to those developed by electronic commerce platforms such as eBay or the Amazon Marketplace. For example, suppose Alicia wants to purchase an item from Ted. Instead of directly paying Ted, she pays the marketplace operator, Oscar who then instructs Ted that he has received the payment and the item should be shipped. After Alicia confirms receipt of the item, Oscar releases the money held in escrow to Ted. This allows the marketplace to adjudicate any dispute that could arise if Ted claims the item has been shipped, but Alice claims not to have received it. Some marketplaces claim to support Bitcoin's recently standardized "multisig" feature which allows a transaction to be redeemed if, e.g., two out of three parties agree on its validity. For instance, Alicia and Ted could agree the funds be transferred without Oscar's explicit OK, which prevents the escrow funds from being lost if the marketplace is seized or Oscar is incapacitated.

Figure 8. Silk road system

Darknet Marketplaces

AlphaBay Market was operating on the Tor network. AlphaBay Market is owned by alpha02 and DeSnake, launched in December 2014. This market was said to be one of the largest Darknet Market tiers around the world. It had 2,40,000 active users on the internet and is devoted to the sale of both legal and non-legal items (i.e. illicit drugs, firearms). Alphabay seized by law enforcement, along with Hansa market.

Dream Market is one of the best Escrow Darknet Marketplace and is established in the year 2013. In Dream Market, you can buy and sell goods from several vendors available on the market. It is a place for buying legal and illegal drug items. Dream Market satisfies both the drugs as well as digital assets. Dream Market drugs have a simple user interface (UI) and high administrative competence

Valhalla Market is a MultiSig or Trusted Invite Darknet Markets. They offer both traditional Escrow and Multisig, 2FA and Forced PGP. Valhalla (Silkkitie) Market recently turned to invite only and require a referral link to register as a buyer or vendor. They were rebranded and now called “Valhalla”. Valhalla Marketplace was established in the year October 2013 as Silkkitie. They started it as a local market for Finland and later became the largest international market ever so far. Silkkitie Market is one of the longest running markets on the Dark Web.

Opioid Sales and the Dark Web

A verification and monitoring service for online pharmacies name **Legit Script** collected data on top dark web drug marketplaces in 2016. A report was prepared for **CSIP** on the state of the internet pharmacy market, including market trends, challenges, and opportunities. The report revealed that approximately 96 percent of websites marketing pharmaceuticals on the open internet — somewhere between 30,000

Table 2. The darknet and drugs

Buyer places orders with the market	Buyer 	Market 	Vendor
Buyer sends Bitcoin to market escrow			
The vendor gets order & escrow confirmation			
Vendor ships product			
Buyer confirms Receipt			
Market releases escrow to the vendor			
Buyer leaves feedback on Market			

and 35,000 — failed to adhere to applicable legal requirements. Of those, the vast majority (all but about five percent) was blatantly illegal and unsafe, selling prescription drugs without requiring a prescription.

The report also revealed that the voluntary efforts of internet and payment platforms such as Google, PayPal, and Bing, among other companies, to curb the online promotion of illicit products have disrupted these illicit businesses' operations, specifically by removing the options of paid advertising and the most common payment methods

Illicit pharmaceutical dealers rely on search engine optimization (SEO) and third-party platforms in lieu of paid advertising. Drug vendors also take advantage of anonymous chat forums to find customers, but the most popular of, reddit.com, has recently seen more scrutiny and enforcement by platform operators.

The surface web is the battleground of an ongoing struggle between drug vendors looking for outlets to market their wares and those trying to stop them, which makes it more difficult for rogue internet pharmacies to maintain a stable presence on the surface web.

LegitScript compiled a list of about 240 marketplaces selling drugs on the dark web, and focused on 12 top marketplaces that sold drugs, including opioids, and were generally online during their research. From these marketplaces they collected data by hand, counting the number of drug listings, the types of drugs sold, the number of vendors for certain opioid products, and the locations from which vendors state they are shipping. Their data and analysis indicate that dark web commerce is concentrated in a handful marketplace and that one, in particular, Dream Market, currently dominates dark web drug commerce.

The anonymity of the dark web makes it ripe for scams, which is why vendor reputation is another pillar of dark web commerce. Customers leave vendor reviews in the same way they might on clear web e-commerce websites such as Amazon or eBay. However, reputation scores take on additional relevance because there is little recourse in the event of fraud. A verification and monitoring service for online pharmacies collected data on top dark web drug marketplaces,

The largest known exit scam is Evolution marketplace, which was abruptly shut down in 2015 and whose operators absconded with \$15 million worth of Bitcoins.

When Alpha bay, the dominant marketplace at the time, was shut down by law enforcement in July 2017, there was wide speculation that its operators had engaged in what would have been a massive exit scam. Some surface web websites track and review dark web marketplaces, rating them by factors such as whether they have had security issues or active warnings, whether they offer security technology such as multisig and two-factor authentication, and whether they have proven reliable and trustworthy.

Heroin comprised 2,294 or 54.6 percent of the opiate listings on Dream Market. The largest subcategories, oxycodone, and fentanyl comprised 11.4 percent and 5.5 percent, respectively. Nine of the 12 marketplaces surveyed broke opioids into subcategories. Of these, heroin was the most prevalent opiate listing in seven. Oxycodone was the second most prevalent opiate listing in four of these nine marketplaces and was first in one.

Prescription drugs on Dream Market are divided into only two subcategories: relaxants and stimulants. Of 2,468 prescription drug listings, 837 (33.9 percent) were classified as stimulants and 213 (8.6 percent) were classified as relaxants. Those not sub-classified fell into neither category, such as erectile dysfunction drugs.

Illicit e-commerce frequently draws vendors who engage in nondelivery schemes, in which sellers receive payment for products they never send. Although this appears to be less of a problem than on the surface web, nondelivery can still occur on the dark web, particularly from vendors targeting inexperienced buyers and from scammers Collaborating with operators of the marketplaces themselves.

Figure 9. Product statistics

Table 3. The 12 dark web marketplaces surveyed by Legitscript

Marketplace	Primary .onion Address	Drug Listings	Opiate Listings
Dream Market	http://lchudifyeqm4ldjj.onion	58,382	4,204

DARK WEB AND THE CARDING ECOSYSTEM

The internet is ripe with stories about travelers who ‘hacked’ their way into cheap travel and vacation costs. In the cybercriminal underground, fraudulent online transactions involving travel documents, airline and hotel loyalty accounts, and other travel-related services have become valued commodities in the past several years. Cybercriminals run this business by offering services paid for using stolen credit cards, hacked loyalty program accounts that were either leaked or vulnerable, and fraudulent redemption of freebies, discounts, and rebates in the form of coupons, among others. Although there are existing security mechanisms in place to combat such illicit activities, cybercriminals continue to offer more and more services in hopes of piquing buyer interest.

The dark web, underground forums, Telegram channels, and even social network postings advertise these services with the intention of providing cheap price tags for those who do not have a problem breaking the law. From arranged travel documents and car rentals to booking flights and hotel rooms, some of the services are offered in the Chinese and Russian underground and some English-language forums:

Digital Shadows' intelligence analysts have identified a Telegram Market gaining traction called "OLIMP". OLIMP has been active since August 2017 looks to provide a new format for buying and selling these goods and services. This is all made easy by the creation of a bot to automate the browsing of these shops. There is a range of items for sale on OLIMP, including discounted hotels, drugs, taxis, documents, and driving licenses. OLIMP has a wide range of items for sale including discounted hotels, drugs, taxis, driver's licenses and documents. For example, the latter offering includes counterfeit press passes for events.

The Dark Web Drawbacks

Because the content on the dark web (often called "hidden services") is not indexed by traditional search engines, and because there is no registration of domain names overseen by a single entity such as the Internet Corporation for Assigned Names and Numbers (ICANN), it's impossible to give a specific, accurate snapshot of content and traffic. Indeed, this is part of what makes the dark web "dark." Hidden services on the dark web are also notoriously slow and unreliable, frequently cycling online and offline multiple times in the same week, or even the same day. A primary reason for this instability is that the dark web is highly decentralized, relying on networks of private servers, which may be something as simple as a person's old laptop. As a result of the way, Tor software works — routing users through multiple relays —the experience of navigating hidden services can be painfully slow.

Tor Metrics collects anonymized data on user's services, and traffic operating through Tor software.

Between April 2017 and March 2018, the number of .onion address ranged from about 45,000 to about 72,000. March 2018, the number was about 68,000. This number does not equate to actual websites on the dark web because hidden services often have multiple .onion addresses. (For example, the dark web marketplace Dream The market has 11 .onion addresses.) Many of these websites may also have no content. In early 2015, Tor Metrics estimated that there were about 30,000 hidden services. The volatility makes it difficult to tell if there is a trend upward. In 2016, .onion Addresses spiked to 114,000. Kate Krauss, Director of Communications and Public Policy for the Tor Project stated that "it's not difficult for even one person—a Researcher, for instance—to create a lot of new onion addresses—which is not the same as actual websites or services. Tor Metrics estimated daily usage of anywhere from about 2 million to close to 5 million.

Dark Web Alternatives

Another weakness of Dark Web marketplaces is their dependence on an operator, or group of operators, who control the sites. Once they're spotted, these persons can be tracked down and prosecuted. The development of decentralized marketplaces such as OpenBazaar generates new challenges that do not exist with Dark Web markets. With OpenBazaar, there is no marketplace operator for law enforcement to target. On the other hand, each individual user engaged in illicit commerce could become a target instead. Decentralized markets are also much harder to shut down.

Since the launch of OpenBazaar 2.0 in late 2017, the network has seen over 100k nodes created and 20k nodes with at least one listing. "Nodes" means the installation of the app and creation of a profile or store that can connect to others on the network and be discovered. OpenBazaar is still in its infancy.

The platform does not anonymize the user by default. Originally, it was entirely on the user to mask their identity if they desired. Now, since the release of OpenBazaar 2.0, users can opt to access the site using a Tor browser, which allows great anonymity. Payments can be made using Bitcoin, but you also have the option to pay using traditional formats.

Figure 10. Open bazaar

Most of the items sold on OpenBazaar are simple consumer goods. On OpenBazaar, you can find items such as food, cigarettes, clothing, and accessories. OpenBazaar is a neutral technology that can be used for many types of transactions. It was not created to cater to any particular type of commerce, such as illicit and illegal goods. Like any technology, much like the Internet itself, the OpenBazaar network reflects society in general: some people will do bad things, most will not.

To locate products on OpenBazaar, you must select a search engine and each search engine will list different products. According to tests, when searching using the OB1 engine, no drugs were found. However, when switching to the Blocktooth engine, a number of cannabis products and other drug-related items were listed. By using different search providers or if you know the vendor's URL, you may be able to access an even wider array of illicit goods. It's impossible to know. Even OpenBazaar has no insight into what is being sold on its platform, and in what numbers.

Counterfeit and stolen merchandise could find a home on OpenBazaar, providing sellers with a level of anonymity that parallels the Dark Web, but using a platform with enough mainstream appeal to increase visibility and reach on the Surface Web over time. Selling counterfeit or stolen goods is possible through OpenBazaar, and if there is such an opportunity there will be those who will want to exploit it.

While the Dark Web and OpenBazaar function in different ways, the outcomes for the seller are quite similar. On OpenBazaar, anyone can sell anything they want. They can mask their identity and hide their location. It is on the side of the user that the real benefits are clear, in that it is much more difficult to scam users in the way that is done on the Dark Web. This can only help the OpenBazaar platform as it establishes itself and evolves to become a viable alternative to the Dark Web. For security professionals, the problem of combating illicit trade continues to become more complex and the number of online locations to monitor more daunting.

Peer-to-peer services such as OpenBazaar remove the middleman and allow illicit operations the best of both worlds: the privacy of the dark web on easily accessible and navigable software. Users can still obfuscate their identities using a VPN. Other decentralized marketplaces include Particle, SysCoin, and BitBay. All of these are powered by blockchain and offer encrypted peer-to-peer messaging for privacy.

Combatting the Dark Web with Technology

On December 6 and 7, 2017, the US Department of Health and Human Services (HHS) hosted its first Code-a-Thon event aimed at leveraging technology and data-driven solutions to help combat the opioid epidemic. The authors—an interdisciplinary team from academia, the private sector, and the US Centers for Disease Control and Prevention—participated in the Code-a-Thon as part of the prevention track.

Objective

The aim of this study was to develop and deploy a methodology using machine learning to accurately detect the marketing and sale of opioids by illicit online sellers via Twitter as part of participation at the HHS Opioid Code-a-Thon event.

Methods

Tweets were collected from the Twitter public application programming interface stream filtered for common prescription opioid keywords in conjunction with participation in the Code-a-Thon from November 15, 2017, to December 5, 2017. An unsupervised machine learning–based approach was developed and used during the Code-a-Thon competition (24 hours) to obtain a summary of the content of the tweets to isolate those clusters associated with illegal online marketing and sale using a bi-term topic model (BTM). After isolating relevant tweets, hyperlinks associated with these tweets were reviewed to assess the characteristics of illegal online sellers.

Results

Researchers collected and analyzed 213,041 tweets over the course of the Code-a-Thon containing keywords codeine, Percocet, Vicodin, Oxycontin, oxycodone, fentanyl, and hydrocodone. Using BTM, 0.32% (692/213,041) tweets were identified as being associated with illegal online marketing and sale of prescription opioids. After removing duplicates and dead links, we identified 34 unique “live” tweets, with 44% (15/34) directing consumers to illicit online pharmacies, 32% (11/34) linked to individual drug sellers, and 21% (7/34) used by marketing affiliates. In addition to offering the “no prescription” sale of opioids, many of these vendors also sold other controlled substances and illicit drugs.

The results of this study are in line with prior studies that have identified social media platforms, including Twitter, as a potential conduit for supply and sale of illicit opioids. To translate these results into action, authors also developed a prototype wireframe for the purposes of detecting, classifying, and reporting illicit online pharmacy tweets selling controlled substances illegally to the US Food and Drug Administration and the US Drug Enforcement Agency. Further development of solutions based on these methods has the potential to proactively alert regulators and law enforcement agencies of illegal opioid sales, while also making the online environment safer for the public.

FUTURE RESEARCH DIRECTIONS AND TRENDS

The anonymity and cryptographic approaches used by dark web visitors impose serious challenges for law enforcement agencies to monitor, investigate, control, and prosecute criminal activities taking part in these darker parts of the internet. Digital Forensics offers methods and tools for identification, collection, analysis, and reporting of information obtained from the dark web in a forensically sound way.

Computer Forensics and Cybercrime Investigation is a fairly new area of research among the more conventional computer security models, there are currently some companies and open-source communities that specialize in forensic investigations. The following represent the most commonly used tools during evidence collection of a digital investigation:

1. **Firewall and Router Logs:** These devices are configured so that they may record any form of suspicious activity.
2. **Packet Sniffing:** This procedure enables the investigator to monitor in real time various activities taking place on a network.
3. **Intrusion Detection Systems (IDS):** Larger networks can sometimes deploy IDS to capture data packets that can be linked to suspicious activities.
4. **Remote Access Servers:** This includes devices, e.g. modem servers and VPN gateways, that facilitate various forms of connections between networks.
5. **Security Event Management Software:** These tools help with the analysis of log files which are typically produced by IDS tools, routers, and firewalls.
6. **Network Forensic Analysis Tools:** These tools are useful in reconstructing events via visualization and replaying of network traffic taking place within a given period of time.
7. **Other Sources:** These sources can include Internet Service Provider (ISP) records, hosts' network connections, and configuration, client/server applications, and Dynamic Host Configuration Protocol (DHCP) record.

Artificial Intelligence and Machine Learning

Machine learning algorithms can help police sweep the dark web and crack down on cybercrime. But beyond evidence of illegal activity, it's helping law enforcement find something far more valuable: motive.

A recent study was conducted with permission from the Australian Federal Police (AFP), by Monash University IT researchers. They conducted an extensive crawl of the dark web to test a classification model named Tor-use Motivation Model (TMM), used to capture user behavior and motivation that can be applied in law enforcement.

Monash University

For legal and ethical considerations, AFP federal agent and Monash Ph.D. candidate Janis Dalins led the research. He emphasized the value of the two organizations working together. In particular, they hoped to draw out not just what kind of material the sites were hosting, but why.

With permission from the federal justice minister, the researchers developed a randomized web crawler that used Tor to access more than 232,000 anonymous pages. Dalins manually classified more than 4000 of these pages according to content and use.

The researchers tested a motivation model using The Onion Router, (TOR), to crawl through thousands of pages of content to classify what it is used for, and how much of it is illegal.

The unrestricted crawl of 200,000 sites showed that two-thirds were illegal and unethical. Of the illegal sites identified, the majority were devoted to the financial activity, such as bitcoin laundering. Other illegal sites included those related to drug commerce and trading of illicit materials such as child pornography.

Nearly 40 percent of the pages analyzed were legitimate. When added to content that was unclear in its intent, it's likely that over half of the material analyzed would not be of interest to law enforcement officials.

Of the illegal material, the most frequently encountered category was a financial crime, at 16 percent of the pages accessed. Of these sites, 95 percent offered products and services for sale, including bitcoin laundering sites and exchanges. Stolen credit cards, bank account details, and gift cards were also on offer.

The follow-up study will focus on applying the classification system to train machine learning algorithms that could be used by police to weed out crime on the dark web and other online platforms in the future.

The results of the study, published in *Digital Investigation*, has shed some light on the dark web highlighting the use of advanced technology giving law enforcement agencies new tools to find - and fight - illegal activity online.

Medical Big Data

Medical Big Data is currently being offered for sale on the dark web. Medical big data relies on medical documentation representing one of the most comprehensive means for collection of information regarding a person's identity, and other personal sensitive private information. The first large-scale theft was recorded by the US Department of Health and Human Services in 2012. In subsequent years, there were more thefts on a similar scale, reaching around a thousand by 2016. In particular, the attention of hackers focused on the theft of personal data, date of birth, addresses of patients, and in particular social security numbers.

Medical information can be worth 10 times more than credit card numbers that are offered for sale on darknet marketplaces. Those who are willing to buy this type of information are mainly fraudsters who can easily use this data to create fake IDs, to buy medical equipment with reimbursement, or even drugs.

Cocaine Delivered Quicker Than Pizza

Professor Adam R Winstock, a consultant psychiatrist and founder of Global Drug Survey, conducted a survey and asked 15,000 cocaine users from around the world whether it was quicker to get a gram of cocaine delivered or a pizza. Overall 30% said they could get cocaine delivered in 30 minutes or less compared to only 16.5% who could get a pizza delivered. There was wide regional variation but in the UK, 80% of recent users reported same day delivery of cocaine being available, with 36.7% of users in Glasgow and 26.7% in London reporting delivery within 30 minutes. Easy access and higher purity are likely to lead to escalating use and harm among people.

Survey findings also revealed that the UK once again had the highest rates (24.6%) of people accessing drugs through the darknet amongst English speaking countries and 3rd overall after Norway (30.3%) and Finland (45.8%). MDMA, followed by cannabis, LSD and novel drugs are the most commonly purchased drugs on the darknet, with notable increases in rates for cannabis and LSD over the last 4 years, with a marching year on year decline in NPS purchase.

SOLUTIONS AND RECOMMENDATIONS

The Dutch law enforcement unit mandated to fight cyber-crime has recruited 14 volunteers comprised of IT experts in order to strengthen the fight against dark web crime. International police organizations like Europol and Interpol are taking dark web crimes very seriously, whereby, in the recent meeting held in Dubai, among the issues discussed was dark web crime. Dutch law enforcement has been at the forefront of the fight against dark web illegal activities. The Dutch detectives were responsible for Operation Bayonet, which took down a popular dark web marketplace known as Hansa.

Existing laws along with the mindset of law enforcement agencies need to evolve to confront the challenges of potential cybercrimes in 2020. In addition, law-enforcement agencies need to upgrade themselves with the latest technologies such as artificial intelligence and robotics to better tackle future cybercrime. Internet protocol (IP) address or source tracing remains a challenge due to the use of proxies, virtual private networks (VPNs) or Tor relay points. A possible solution to this might be an allocation of IPv6 addresses on an individual basis. If every user is allocated an IPv6 address, which is required to connect to the internet, it will eliminate the issue of IP tracing. A combination of increased user awareness and use of advanced technologies for defense will go a long way in helping individuals and enforcement agencies deal with the future of cybercrime.

Rather than shaping technology to conform to international law based on national sovereignty, countries can find new ways of enforcing existing laws. For example, cooperation on investigations of cross-border data flows would allow law enforcement to respond to threats more quickly.

Countries might exercise sovereignty rights for setting their specific rules with respect to when data should be stored and processed by different authorities for reliable and legitimate purposes. It is important for authorities to be on their toes in safeguarding the same from future unknown hacking techniques.

CONCLUSION

November 1, 2017, Finnish Customs in collaboration with the police shut down the Sipulikanava website. This marked the biggest ever shut down in the country. The accused are two Finnish nationals and one a 45-year-old IT wizard who also was the Sipulikanava website's administrator. This case also marks the first time, the administrator of a dark web marketplace is being accused of dealing large quantities of narcotics online.

With advancements in digitization and organizations, individuals, as well as defense establishments, would be potential targets of cybercriminal activities. The rise of cybercrime in the current year serves as a great signal for the incrementing societal engagement in issues of data protection and internet governance. It is assumed that citizens will demand greater transparency as well as accountability from the governments and service providers, and even some kind of data autonomy. Taking a cue from Europe's General Data Protection Regulation (GDPR), it is important for governments and businesses to understand that an individual's data is his or her asset and eventually individual's rights can be exercised under a mature regulated environment. Therefore it is important for increased data protection and governance culture. As new technologies like the internet of things continue to evolve, the ability of international law to combat their negative uses becomes increasingly important.

The Dark Web: Hidden Access to Internet Today

1

Thiagarajar College of Engineering, India

INTRODUCTION

Internet is a hardware asset consists of multiple nodes where each node is a server/ client systems such as laptops, computers, etc. In earlier days, the data are transferred or shared using the Internet. In 1994, Berners-Lee et al introduced web in which the data are accessed through hyperlink text or web pages. Web is software which runs over the internet to provide the service to users. Only 4-6% of the whole web or the web pages (surface web) are indexed in search engines such as Google, yahoo, etc. However, web which is not indexed in search engines is 400 times larger than surface web also known as deep web. The deep web (Bergman, 2001) can only be accessed through a special link or with special permission to access the data in the cloud or specialized servers which cannot be found on any of search engines. Government sectors, private bank data, cloud data, etc are examples of the deep web. The data in the deep web are so sensitive and private which are to be kept in secret. These data are allowed to access only by specific people. There is a subset of deep web termed as dark web (Chen et al, 2008). Figure 1 shows the difference of Surface web, Deep web and Dark web.

Dark web allows a user to host a website on a specific network termed as dark net which remains anonymous always. The network used by the user to maintain anonymity is dark net. Dark net is a network build over the internet which is completely encrypted. Traditionally, when a user visits any sites,

Figure 1. Difference of surface web, deep web and dark web

DOI: 10.4018/978-1-5225-9715-5.ch008

they are tracked via their Internet Protocol (IP) address. However, the dark net maintains privacy through specialized anonymity software and configurations to access. One such dark net is Tor (“The Onion Routing” project) (Dingledine et al, 2004).

TOR AND DARK WEB

The TOR architecture provides two basic services – anonymous browsing and hosting of anonymous information exchanges. These services are provided by one piece of special software – ‘Tor Browser’. There is no special technical requirement for these services to be bundled. Indeed, browsing is more popular than hosting. No Tor users have visited any hidden website at a *.onion address. Most probably, all the users merely use Tor browser to browse the internet’s conventional address space more securely. For example, Mary, who lives in a small town, wants to buy a pregnancy test but doesn’t want to be seen doing so by the shop owner. Peter, a friend of Mary’s father, wears a mask, walks detours and pay in cash. Peter will not be able to identify or trace. Also, Mary’s privacy and anonymity are assured. Anonymous browsing is not actually a part of ‘dark web’, but it is a legitimate and impressive service provided by Tor. The underlying purpose was to create a distributed, anonymous easily deployable and encrypted network to be used by those who needed it. Specifically, it was offered as a free service to promote unfettered access to the internet in locations where online censorship was heavily enforced. Chaum in 2003 provided a way for this access through onion routing. In order for a user to access the website securely, the person has to be routed through a series of intermediary servers. The resulting pathways between servers were labeled ‘circuits’. Each packet of information to be relayed over the network would be encased in multiple layers of encryption, each to be sequentially peeled away only by the subsequent node in the circuit. Consequently, intermediary nodes could only decrypt one layer of the encryption, preventing access to the underlying data and its originator. The final such hop – or exit node – would reveal the original packet and proceed to deliver it to the desired destination, thus protecting the sender’s identity. As a result, intercepting and decoding the information along its path would be significantly harder – albeit not impossible – to accomplish. The dark web attracted the people who do illegal stuff such as trade, forums, media exchange for terrorists, etc. without getting caught. “Silk Road” is a dark web site which is used to sell drugs and was taken down already by FBI (Cubrilovic, 2014). Friend-Friend and Free net is also a dark web provided by darknet used to transfer file anonymously.

THE SIZE OF THE DARK WEB ECONOMY

The dark web, an ocean of illicit activity often carried out by persons to trade stolen data, dollars, etc. In 2016, the economist reported that usage of dark web by drug side grew from \$15 in 2012 to approximately \$225 million in 2019. On estimating the world economy, the dark web has frustrated every attempt of money and other information transactions. In the year 2023, the dark web cybercrime will be an increase of 175% increase as reported by Juniper research. Dark web is increasingly used by hackers like hire, hitmen and other service providers who can’t advertise over traditional channels. Also, the year 2017 has been recognized as the most notorious year for selling ransomware for Dark web. Even a casual news consumer can feel the ransomware attacks cost an estimated worldwide business of \$1 billion this

year. *Carbon Black's Threat Analysis Unit (TAU)* has investigated the deepest, darkest portion on the web, where ransomware is currently being created, bought and sold in rapidly increasing underground economies. The research has found that in the financial year 2018-2019 there has been 36.5% increase in the sale of ransomware on the dark web. The research found that, in the financial year 2016-2017, there has been a 25.2% increase in the sale of ransomware on the dark web. This large scale increase is due to supply and demand of the world's economy. Cybercriminals are progressively looking for more opportunities to enter the market and to make quick money via any one of the many ransomware offerings available via illicit economies. In addition, a basic plan of ransomware is its turnkey. Unlike other forms of cyberattacks, ransomware can be quickly deployed with a high probability of profit. The interesting information is, the dark web economies are also empowering even the most novice criminals to launch ransomware attacks via do-it-yourself kits and providing successful ransomware researchers with annual incomes into six figures.

KEY FINDINGS OF DARKWEB RANSOWARE

- Currently more than 63,000 dark web marketplaces are selling ransomware with 45,000 product listings. The prices for the do-it-yourself (DIY) kits range from \$0.50 to \$3K.
- Comparing to the year 2016 target, the ransomware marketplace of 2017 on the dark web has grown to a rate of 2,502%. According to the FBI, ransom payments totaled about \$1B in 2016, which was \$24M in 2015.
- According to figures from Payscale.com, ransomware sellers are making more than \$100,000 per year simply retailing ransomware, however, the legitimate developers earn only to a maximum of \$69000.
- The most notable innovations contributing to the success of dark web ransomware economy has been the emergence of Bitcoin for payment, Tor for anonymity network.
- Ransomware sellers are increasingly specializing in a specific area of the supply chain, further contributing to ransomware's boom and economy development.

REGULATING THE DARK WEB

To regulate the dark web, the regulators have struggled a lot with enforcement. In 2013, FBI has taken down Silk Road (Van Hout et al, 2013), a popular drug market of the dark web in 2013. Silk Road 2 popped up in 2014 before FBI has taken up Silk Road. Silk Road 3 followed of course. In addition to difficulty in stamping out new marketplaces, OpenBazaar has provided opensource code which allows for decentralized marketplaces similar to how torrents allow for decentralized file sharing. So, the dark web economy continues to grow despite the best efforts of law enforcement. A recent study from researchers at King's College London gives the following breakdown of content by an alternative category set, highlighting the illicit use of ".onion" services for the access of Dark webs. The objective of the proposed chapter is also to exploit the illegal access of Dark nets g, through webs and the benefited user through the webs. Also, this chapter explains about the actions taken by the National agencies like cybercrime and cybersecurity office (Manikandakumar et al, 2018) towards the Dark web.

ILLICIT USE OF “ONION” SERVICES

Botnets

Botnets (Barford et al, 2007) are one of the major threats faced by Internet users. Hackers mostly used botnets for many kinds of malicious activities or to spread malicious activities such as DDoS attacks, phishing attacks, personal data theft, spam, bitcoin mining, and cyber-espionage. Traditionally, botnets used centralized overlay networks where the Command-and-Control(C&C) acts as a single point of control. In case of failure, or taking down C&C servers, the whole botnet will be defeated. Hence, Botmasters have recently focused their attention to the Tor network to provide the botnet C&C servers with anonymity. The advantages of botnets over the Tor network may provide

- High availability and low downtime of authenticated hidden services
- Reasonable availability of private networks
- Debug node flooding capabilities.

The use of Tor network to hide botnet infrastructures evolved during 2010. Brown in 2010, has provided the first demonstration of C&C servers and its applications through Tor network to provide anonymity. Guarnieri, 2012 has first identified a mechanism to detect and analyze the first Tor-based botnet. The modified version of a botnet with Zeus enables the user to do illegal stuff such as bitcoin mining and credential thefts. The malware designed by any hacker with Zeus bot, Tor client, and few libraries for GPU crash any number of systems. Later in 2013, the Tor mailing list (Munson, 2013) raised the attention of hackers to use huge networks and users in real-time processing. Due to the enormous usage of Tor networks, computational overload caused the expensive encryption operations to have reduced the responsiveness of the system.

Bitcoin Services

Bitcoin (Nakamoto, 2008) uses a peer-to-peer technology (P2P digital currency) to operate with no central authority such as banks or under any Government agencies. Transactions and issuing of coins are managed by over collective of the distributed network. The anonymity is provided by random-looking Bitcoin addresses, however, the level of anonymity is very low as suggested in various research (Biryukov et al, 2015). This encourages the Bitcoin users to use the network through dark nets such as the Tor network. Dark web and the Bitcoin have a strong relationship, as Bitcoin is often used on the dark web. Most of the e-commerce sites on dark nets allow users to do any kind transactions to buy and sell goods using Bitcoin. The Silk Road (Vanhout et al, 2013) is one of the most famous darknet sites specialized in purchasing drugs with Bitcoin. All over the world, there are 12 Bitcoin related cases filed. Seven of them operate on Silk Road, which involves the owner of the Silk Road and his employees, drug vendors, and Bitcoin vendors operating on this site. Finally, two FBI agents were charged for money laundering and wire fraud. The vendor who needs to sell any drugs in Silk Road, they must be aware of the following. Initially, the vendor who needs to do any transaction on dark nets with Bitcoin must have enough knowledge of Tor service to access Silk Road. Second, they have to create a store on the Silk Road. As like e-commerce sites Amazon, Flipkart, Silk Road provides a system to rank the vendors base on the quality and frequent purchase by customers. It also allows the customer to leave a comment using a five-star rating system. The drug vendors Sadler and White did the online drug business for more

than one year and ranked no 1 among top sellers. Also, there were 142 customer feedback pages rating with mostly 5 stars. In addition to a ranking system to the customer, Silk Road launched a “4/20” scale a free paid trip to Thailand with a total cost of approximately \$30,000. The final step of any vendor is to acquire bitcoin and prepare an address for delivery. If buyers didn’t have any Bitcoins they can avail Bitcoin exchange service to change their fiat currency to any Bitcoin. The fourth step is the delivery and payment. To prevent controlled delivery, Silk Road provides detailed guidelines to help their customers from further investigations. To avoid from regular postal investigations with sniffer dogs, vendors used a vacuum-sealed and zip lock cover to seal the drugs. Silk Road uses a special system for payment. The buyers who purchased any drugs transfer their bitcoin through online once received by the vendors, they will deliver the products.

Crypto Markets

Crypto markets (Martin, 2014) are online commercial websites or marketplaces that are part of dark web operate via dark net such as Tor or I2P. The main objective of crypto markets is for the sale of illicit drugs, whole sale black markets, brokering transactions on drugs, cyber-arms, steroids. They provide tools for anonymity to the participants with the purchase and delivery of products through illicit drug trafficking. Following the Silk Road model, crypto markets are characterized by their usage of darknet anonymized access and bitcoin payment with escrow services. Canada was in Top 5 of the most frequent shipping on Silk Road, with 6% of the listing originated from Canada. The paper Broseus et al, 2016 reports, Agora, Silk Road2, and Evolution are three main crypto markets in terms of their number of vendors and customers active on them and products on sale. None of these crypto markets are currently running due to certain reasons (Gibbs, 2018). The Table 1 values are referred from Broséus et al, 2016. The Table 2 list the product often purchase through crypto markets and their break down ratio.

Hacking Groups and Services

The dark web is one of the most charming remnants of humanity, aggregated marsh of all the darkest aspects of internet activity such as child abuse images (kiss, 2013), drug markets, gun shops, gore smut, stolen merchandise, anarchist guides, terrorist chats, identity theft, hacking services and even more. The following describes about the potent of using these services for hacking (Marin et al, 2016). The

Table 1. Number of vendors and listings originating from Canada

Crypto markets	Number of Vendors	Number of listings
Agora	57	1109
Evolution	44	691
Silk Road 2	36	748
Cloud Nine	27	395
Pandora	18	398
Hydra	8	79
Andromeda	5	149
Blue sky	3	116
Total	198	3685

Table 2. Vendor product breakdown as on 3 June 2016

S.No	Product	Breakdown (%)
1	Cannabis	31.6
2	Pharmaceuticals	21.05
3	3,4-Methylene Dioxy Methamphet Amine (MDMA)	10.530
4	Lysergic acid diethylamide (LSD)	5.26
5	Methamphetamine	5.26
6	Mushrooms	5.26
7	Heroin	5.26
8	Seeds	5.26
9	Video Games	5.26
10	Accounts	5.26

user what actually think is “Browsing porn in incognito mode isn’t nearly as private as you think”. One of the largest hacking forums on the internet which uses the concept of Dark web is FreeHacks. It’s a Russian community which aims to collectively gather its resources in order to maximize efficiency and knowledge dispersement. It works similar to any typical forum, as like opening the Tor browser, copy and paste the URL, and land on a home page with various sub-forums. The sub forums are of varied and well divide into different categories as like

- Hacker world news
- Humor
- Hacking and security
- Carding (stealing credit cards and trying to cash them out on the internet)
- Botnet (a network of bots used to steal data and send spam, or perform DDOS attacks)
- Electronics and phreaking (phreaking is trying to break someone’s security network)
- Brutus (software used to crack passwords)
- DDOS (overwhelming a server with requests to shut it down)
- SEO-optimization
- Programming
- Web development
- Malware and exploits
- Private software
- Clothing market (people who use stolen credit cards to buy clothes and resell them)
- Financial operations
- Documentation (passports, driving licenses, citizenships)
- Blacklist (a community judicial system).

The above mentioned illegal activity covers a dizzying amount of information, from a Russian forum and has more than about 5,000 active members. This is just the overview; even every sub-forum is further splitted into dozens of other sub-forums. When a user attempts to register on any hacking site, you’re met with a mission statement of sorts – a weird justification method for their own illegal activities. Once you

go through the rigorous registration process where you have to declare why you want to join the forum, and what software development skills you have and want to learn, you are granted access to this treasure trove of illicit information. It seems more pathological and ironic; these hackers who essentially get paid to make life more difficult for people try to justify it with a fascinating proclamation.

The word 'hacker' is incorrectly used in the meaning of 'computer burglar' by some journalists. However, hackers, refuse to accept such an interpretation of it and continue to imply the meaning of 'someone who likes to program and enjoy it'

FRAUD SERVICES

In recent days, more number of fraudulent services (Moore et al, 2016) has emerged such as falsification of documents, forgery or counterfeit are types of fraud. The theft of one's personal information, like social security number or identity is type of fraud. Fraud can be communicated through many media includes mail, wire, phone and the internet may be computer fraud and internet fraud. However, in dark web, fraudulent refund services are now becoming another fierce of attack for malicious actors (Alrwais et al, 2014). The malicious actors' targets online retailers, banking sectors on their generous refund policies to fraudulently claim money or replacements for products they hadn't purchased. These services are particularly persistent form of a cybercrime since merchants are stuck between trying to ensure customer satisfaction and mitigating the loss of an estimated 50,000 Euros every month through cybercrime. For an example, a typical fraud case occurs when the false buyer claims that the product they allegedly purchased has never arrived. Due to the severe competition going on between online retailers, many of them promptly respond to such claims with the refunds or replacements purely to control damage to their reputation and to keep the customer happy.

Refund fraudulent services have grown significantly since 2017, coasting on the increasing number of online sales. Refund services are openly discussed on the dark web forums where fraudulent vendors are quick to offer their "specialized services" to the interested third parties. In return for effective service, these illegal vendors gain enormous followings and create a reputation that is conducive to the continuity of their business. Happy customers have been known to go as far as leaving screenshots alongside messages of gratitude and praise following a successful refund scam. Vendors who pull off scam after scam successfully will often receive repeat business from many of their customers, who are sometimes satisfied enough to leave positive reviews about their experience. Even as online retailers struggle to figure out a way around this scam, more and more illicit vendors pop up on these dark web forums offering their services.

This kind of increase in criminal activity has led to an invasion in the advertisement of fraudulent receipts on the dark web. These fake receipts (Baravalle et al, 2016) often look as authentic as the next and can be engineered to target a wide variety of online retailers. Fake receipt vendors rely on social engineering as their main approach since there are no parameters to be bypassed in this scenario. The customizable nature of these fake receipts only makes it more difficult for companies to preempt these actors next move. These receipts also present a huge problem for many online stores as Flashpoint analysts cautiously predict. In addition to saturating the market with an indeterminate number of fake receipts, these illicit vendors have made it easier for malicious actors to claim reimbursement even without making the initial purchase. Similarly, they have made it increasingly difficult for companies to spot instances of fraud even if they're perpetrated by the same person.

The availability of physical fake receipts will make it harder for stores to suspend people from using them to wrongfully claim reimbursement. As an added risk, the physical receipts will make it impossible for the retailers to avoid reimbursing customers for stolen products. Several illicit vendors offer digital and virtual receipts alongside product serial numbers just to increase the legitimacy of the claim. Aside from the very pertinent concern of having a market that is flooded with fake serial numbers, the availability of fake product serial numbers leads Flashpoint analysts to speculate that these vendors are in possession of the serial number-generating software. Already, several of these types of software have been spotted on various forums both on the dark web and on the surface web.

Increase in the competition between the online retailers and a need for transparency will continue to force retailers to extend munificent policies, usually at their own expense. This gap is one that may only widen a business's compete to differentiate themselves and to build loyal customer bases. As miserable as the situation appears to be, online businesses can avoid falling for some of these fraudulent claims by carefully analyzing all refund claims before fulfilling them. A dedicated intelligence service can facilitate this and help businesses to avoid massive losses from cybercrime.

Hoaxes and Unverified Content

An assassination market (Moore et al, 2016) is a prediction market where any party can place a bet (using anonymous electronic money and pseudonymous remailers) on the date of death of a given individual, and collect a payoff if they “guess” the date accurately. This would incentivize assassination of individuals because the assassin, knowing when the action would take place, could profit by making an accurate bet on the time of the subject's death. Because the payoff is for accurately picking the date rather than performing the action of the assassin, it is substantially more difficult to assign criminal liability for the assassination. There are reports of crowd funded assassinations and hitmen for hire, however, these are believed to be exclusively scams. The creator of Silk Road, Ross Ulbricht, was arrested by Homeland Security investigations (HSI) for his site and allegedly hiring a hitman to kill six people, although the charges were later dropped.

There is an urban legend that one can find live murder on the dark web. The term “*Red Room*” (Drazen, 2014) has been coined based on the Japanese animation and urban legend of the same name. However, the evidence points toward all reported instances being hoaxes. On June 25, 2015, the indie game *Sad Satan* was reviewed by Youtubers *Obscure Horror Corner* which they claimed to have found via the dark web. Various inconsistencies in the channel's reporting cast doubt on the reported version of events. There are several websites which analyze and monitor the deep web and dark web for threat intelligence, for example Sixgill.

Phishing and Scams

A phishing website (sometimes called a “spoofed” site Zarras et al, 2014) tries to steal your account password or other confidential information by tricking you into believing you're on a legitimate website. You could even land on a phishing site by mistyping a URL (web address). Phishing via cloned websites (Elangovan et al, 2019) and other scam sites are numerous, with darknet markets often advertised with fraudulent URLs.

Puzzles

1

Puzzles such as Cicada 3301 and successors will sometimes use hidden services in order to more anonymously provide clues, often increasing speculation as to the identity of their creators.

Illegal and Ethically Disputed Pornography

There is regular law enforcement action against sites distributing child pornography – often via compromising the site by distributing malware to the users (Mark, 2014). Sites use complex systems of guides, forums and community regulation. Other content includes sexualized torture and killing of animals and revenge porn.

Terrorism

There are at least some real and fraudulent websites claiming to be used by the Islamic State of Iraq and the Levant (ISIL) previously ISIS, including a fake one seized in Operation Onymous (Weimann, 2016). In the wake of the November 2015 Paris attacks, an actual such site was hacked by an Anonymous affiliated hacker group GhostSec and replaced with an advert for Prozac. The Rawti Shax Islamist group was found to be operating on the dark web at one time.

Social Media

Within the dark web, there exist emerging social media platforms similar to those on the World Wide Web. Facebook and other traditional social media platforms have begun to make dark-web versions of their websites to address problems associated with the traditional platforms and to continue their service in all areas of the World Wide Web.

CONCLUSION

The deep web will continue to perplex and fascinate everyone who uses the internet. It contains an enthralling amount of knowledge that could help us evolve technologically and as a species when connected to other bits of information. And of course, it's darker side will always be lurking too, just as it always does in human nature. The deep web speaks to the fathomless, scattered potential of not only the internet but the human race, too. Regardless of if the Dark Web exists or not, the aforementioned activities still occur. The Dark Web just provides an easy way to connect with people of similar interests and to facilitate further interaction.

Privacy, Ethics, and the Dark Web

Richard T. Herschel

Saint Joseph's University, USA

INTRODUCTION

Online activities that have compromised people's privacy has led to the creation of legislation that is intended to protect privacy rights. These decrees represent an attempt by law enforcement and government officials to more forcefully address immoral patterns of online behavior that are effectively compromising the safety of society. Two primary examples of this new legislation are the European Union's General Data Protection Regulation [GDPR] and the California Consumer Privacy Act. Both detail rules and procedures that organizations must follow when handling the personal information that they collect online as well as the rights afforded to the individual in the management of their digital identity.

The GDPR states that EU citizens have the right to information about them that is being collected by organizations as well as how it is being processed. They can ask that incorrect, inaccurate, or incomplete personal data be corrected or that their personal data be erased. Individuals can restrict the processing of their personal data for marketing purposes or for any other given situation they deem necessary. People can even request that decisions based on automated processing concerning them be made by people, not only by computers (EU Commission (1), 2018). The GDPR defines personal data to include any information generated by organizations that monitors citizen behavior and generates personal information. This includes all forms of tracking and profiling on the internet, including for the purposes of behavioral advertising.

California has passed new consumer-privacy legislation that is somewhat similar to the GDPR - California Consumer Privacy Act, A.B. 375. This law is the first of its kind in the United States. The California regulation requires businesses to offer consumers options to opt out of the sharing of their personal information, and it gives Californians the right to prohibit the sale of their personal data. The law also forbids retailers from treating customers who opt out of data sharing any differently from those who don't, suggesting the possibility that this provision could end loyalty programs that offer discounts to members. The regulation broadens the definition of what constitutes personal information and it gives enforcement power to the California attorney general (Vartabedian, Wells, and O'Reilly (2018).

While these legislative actions are intended to constrain organizations in their use of personal information collected online, there remains a high probability that continuing attempts will be made to compromise data privacy. Specifically, the illicit activities of entities employing the Dark Web present an ongoing and much more serious challenge to the protection of privacy rights than do the activities of legitimate organizations engaged in online business transactions.

Primarily off the mainstream radar until recently, the Dark Web is viewed by many as a haven for those who engage in unscrupulous behavior. Yet, at the same time it can also provide an important safe harbor for those engaging in whistleblowing activity. This paper examines the challenges that the Dark Web presents for society, its impact on privacy rights, and the ethical challenges that require organizations to be vigilant in order to minimize threats to both their clientele and to their operations. The paper also examines the important role that ethical theories play in shaping our views about Dark Web activities.

BACKGROUND

1

Hartnett (2017) states that when someone refers to doing online research on a topic or they are looking for other online information, they typically use search engines such as Google, Yahoo, Safari, and Bing. These applications employ information on the public [or surface] web, which represents only 4% of web content (~8 billion pages). The Deep Web refers to the other 96% of the digital universe that is basically hidden. Wolford (2018) notes that this is the bulk of the Internet and it differs from the surface internet that most people know and use, because it is not indexed by search engines. He reports that the Deep Web includes content such as financial databases, web archives, and secured documents.

Hewilson (2018) provides some interesting statistics about the Deep Web. The author reports that:

- the Deep Web contains 7500 terabytes of information where the surface web, in comparison, contains 19 terabytes of content,
- the Deep Web has between 400 and 550 times more public information than the surface web,
- more than 200,000 Deep Web sites currently exist,
- together, the 60 largest Deep Web sites contain around 750 terabytes of data, surpassing the size of the entire surface web 40 times,
- 550 billion individual documents can be found on the Deep Web compared to the Surface Web's 1 billion individual documents, and
- 95% of the Deep Web is publicly accessible, meaning no fees or subscriptions.

Pagliery (2014) contends that the vast majority of the Deep Web holds pages with valuable information. He states that 54% of Deep Web websites are databases. These include, he states, those of the U.S. National Oceanic and Atmospheric Administration, NASA, the Patent and Trademark, and the Securities and Exchange Commission's EDGAR search system -- all of which are public. However, it also includes, he notes, pages kept private by companies that charge a fee to see them, like the government documents on LexusNexus and Westlaw or the academic journals on Elsevier.

The Dark Web of the Deep Web

Embedded in the Deep Web is the Dark Web. Chertoff (2017) states that The Dark Web is a very small, hard-to-access portion of the Deep Web. He says that it accounts for less than 0.01% of the sites on the Internet. Bischoff (2018) agrees that the Dark Net is a small part of the Deep Web. In the Dark Web, he asserts, are users who are deliberate in their desire to be free from the prying eyes of governments and corporations because they deliberately need to mask their identities and as well as their illicit activities.

The British Computing Society (2017) describes what some of these unscrupulous activities include:

- **Forums:** They state that discussion forums here provide a way for criminals and other people to communicate and share information with each other. They assert that many criminal conspiracies are in all likelihood planned and carried out because of conversations which take place on the Dark Web forums.
- Software downloads and serial key sharing. Downloading illegal software, and sharing serial keys is commonplace throughout the Dark Web, allowing some people to gain access to software for nothing.

- **Hackers:** The Dark Web is a marketplace for hackers to buy and sell their services, as well as to talk. Here hackers communicate with people who want to buy their services, commonly via forums.
- **Illegal Items of all Types:** The Dark Web marketplace offers everything from hitmen to drugs to counterfeit currency.

HuntSource (2018) notes that contrary to popular belief, browsing the Dark Web is not illegal in and of itself, unless you access sites with forbidden content or purchase contraband, stolen or forbidden products in the plethora of digital marketplaces that are found there. Glance (2018) reports that “darknet markets” sell illegal products like drugs and firearms, paid for in the cryptocurrency Bitcoin. In addition, he says it is a place used by pedophile groups, terrorists, and criminals to keep their dealings secret and it is the place of choice for groups wanting to stay hidden online from governments and law enforcement agencies and where whistleblowers communicate with journalists.

Stack’s (2018) data provides an interesting list of the most common pieces of information sold on the Dark Web and their prices:

- Social security number \$1
- Online payment services login info \$20-\$200
- Driver’s License \$20
- Loyalty Accounts \$20
- Diplomas \$100-400
- Passports (U.S.) 1000-2000
- Credit or debit cards: \$5 with CVV number, \$15 with Bank info, \$30 with complete detailed information
- General non-financial institution logins \$1
- Subscription services \$1-\$10

Medical records \$1-\$1000

Osborne (2018) says that stolen airline mileage is also offered for sale on the Dark Web at a fraction of its true cost -to the detriment of their true owners. Osborne reports that 100,000 BA air miles were found for sale at the price of €124 (\$144); 45,000 Delta SkyMiles could be bought for \$101; 100,000 Emirates Skywards points could be purchased for \$520, and \$884 would buy you 100,000 Virgin Atlantic Flying Club points. These air miles are offered for purchase using cryptocurrency (e.g., Bitcoin).

Brewster (2018) reports that a recently developed map of the Dark Web shows 6,608 dark web sites crawled during January of 2018. He states that this includes all manner of webpages, from the amusing to the horrific. Amongst the myriad pages on the map, he says there is clear evidence of extreme sexual content, credit card cloning products, a large number of Bitcoin scams, and an assortment of whistleblower pages.

C.M. (2018) concurs that the emergence of the Dark Web has led to increasingly malicious activities on the Internet that has impacted the effectiveness of cybersecurity and Internet governance. He argues that cybersecurity aims to protect information systems and data for any organization, while Internet governance is comprised of the evolving policies and rules under which online users make decisions on Internet use and development. These two bodies have been put in place to ensure that the integrity of the use of the Internet is considered by any user and to ensure that no illegal operations take place.

However, on the Dark Web, he states, ill-intentioned entities can transmit false information and even plan unlawful attacks against a government, and this creates challenges to their Internet governance and cybersecurity control centers. And, C.M. reports that further compounding the problem is the fact that the number of hackers carrying out their activities on the Dark Web is rapidly rising and more people are employing the use of cyberattack services or even learning how to manage it for themselves without being tracked. The bottom line is that the Dark Web provides a favorable environment for conducting illegal businesses and this reduces trust in all forms of business conducted on the Internet.

PRIVACY PROTECTION AND THE DARK WEB

Because of the vulnerability that the Deep Web presents for organizations, it can become a complicating factor in establishing GDPR compliance. If, for example, personal data held by a firm is hacked and then the data leaked, organizations must make every effort to inform the EU of the suspected breach, assuming that they themselves are aware that it has occurred. Once data appears on the Dark Web, it may be ruled as visible under the GDPR and be grounds for penalization.

Bonilla (2018) notes that as data grows in value, attempted cybersecurity breaches for the sake of mining sensitive information will only increase. With many networks having loopholes that can be exploited quietly by hackers using techniques such as phishing, data can be stolen without any major signs that a breach occurred. This means that to maintain compliance with the GDPR, firms will have to proactively determine if those whose data they collect have ever been the victim of a data breach. And, he notes, that is easier said than done.

PAConsulting (2018) states that the National Security Agency (NSA) and UK Government Communications Headquarters (GCHQ) have devoted considerable effort and resources to infiltrating what occurs on the Dark Web. But in response to this, PAConsulting reports that Dark Web activists who want to stop government ‘spying’ on people are developing a wide range of tools to thwart this infiltration. These protesters are advocating the use of strong cryptography and privacy-enhancing technologies – software that ensures complete anonymity in activities that activists employ to foster social and political change. However, PAConsulting notes that criminal groups and terrorists will also use these tools to commit illegal acts undetected.

The widespread availability of Dark Web forums dedicated to freely sharing privacy-enabling technologies, intrusion software, and exploitable code means that global law enforcement agencies face an uphill struggle. PAConsulting reports that the sheer complexity of the Dark Web means it is unlikely that hacktivist groups will be regulated any time soon. In the meantime, criminal groups can arm themselves with freely-available technologies that are making their job even easier, and their victims’ job all that more difficult. PAConsulting concludes there is a growing number of technically-savvy ‘amateur hackers’ carrying out cyber-attacks, though with relatively little impact. But they caution businesses to be wary that even the average customer could buy a cyber-attack service anonymously – or possibly learn to conduct their own cyber-attack – without being caught.

Kang (2018) states that companies and individuals that don’t have the ability to monitor the Dark Web for stolen information can turn to specialized entities and agencies that do. He notes that the credit monitoring company Experian recently launched a Dark Web monitoring service for individuals and he indicates that other companies may soon follow suit. He reports that businesses have more options. He notes, for example, that the National Cyber & Forensics Training Alliance, a nonprofit information sharing organization affiliated with the FBI offers a free Internet Fraud Alert program that provides busi-

nesses with a degree of Dark Web monitoring. Companies requiring personalized levels of monitoring can pay for services from a number of forensic firms.

Kang offers that if individuals and companies learn that their personal or business information has been spotted on the Dark Web, their next step is to minimize damage. He says that individuals can change login passwords or cancel compromised financial accounts and businesses can similarly instruct employees to change compromised credentials, and they can begin investigating their company's systems for infiltration in order to plug holes. Finally, Kang says, that knowing you're your company's (or personal) information was stolen gives a reason to contact law enforcement. He encourages victims to report theft of online information to organizations like the FBI. He says that they can do this at either an FBI Office or online via the Internet Crime Complaint Center. He urges both individuals and businesses to do so, because providing this information may help law enforcement to develop trends and patterns to find criminal actors.

Kang (2018) does acknowledge that in the right hands, the Dark Web can be used to foster positive social change. For example, he notes that democracy activists in foreign countries have used the anonymity of the Dark Web to organize their activities and, he says, the United States State Department has invested time and resources to encourage this use of the Dark Web.

Corse (2018) reports that with elections, one issue looms large for voters and election officials alike: cybersecurity. Hoping to quell fears about foreign hackers and repel potential threats, he reports that many states and counties are beefing up their plans to deal with cyberattacks. Corse says that they work to shore up systems to protect voter databases, hiring security experts to assess the strength of their defenses. He reports that officials coordinate with social-media organizations to stamp out deliberately fraudulent messages that could mislead voters about how to cast a ballot. And, he says, they band together to share information and simulate how they would respond to potential emergencies. Course reports that one simulation-based exercise, held by the Department of Homeland Security in mid-August of 2018, gathered officials from 44 states, the District of Columbia and multiple federal agencies.

The cost of protecting privacy is significant. Steve (2018) reports that the government of Canada is allocating one billion dollars to their federal budget to be spent on the fight against cybercrime. The Republic of Canada in the recent past has experienced an increased number of cyberattacks directed at its vital institutions, including hospital networks and government agencies. Officials fully expect that hackers will continue to engage in cybercrime activities via the Dark Web.

Pepper (2018) reports that Australia has introduced an Assistance and Access Bill to secure critical support from the communications industry that will enable law enforcement to effectively investigate serious online criminal activity. The legislation notes that encryption conceals the content of communications and data held on devices, as well as the identity of users and that secure encrypted communications are increasingly being used by terrorist groups and organized criminals to avoid detection and disruption. Pepper states that the bill seeks to grant the Australian authorities' clear powers to carry out stealthy surveillance activities on electronic devices and it prompts tech organizations to cooperate in decrypting private communications.

Thales (2018) provides data that reveals how challenged organizations are in dealing with threats to the privacy of their information. They conducted a poll of 1,200 organizations that revealed the following descriptive statistics concerning privacy protection issues:

- 42% of enterprises breached this year had been breached in the past.
- 79% increased IT security spending – and the data breaches didn't even slow down.

- 78% of the organizations plan increasing security spending in 2018, including 86% of U.S. organizations, up from 73% globally in 2017.
- Percentage of global organizations who state that they will not be impacted by data privacy/sovereignty regulations (e.g., GDPR) was 28% 2017, 13% in 2018

OWL Cybersecurity (2018) employed data and analytics to generate a darknet footprint of Fortune 500 companies that provides a snapshot view of each company's exposure on the darknet relative to its peers. Their analyses revealed that the highest scoring companies all had credentials and/or intellectual property exposed on the darknet that could be monetized by others. They also discovered that every Fortune 500 company had a positive darknet Index score, meaning they have a presence on the darknet. The company with the largest darknet footprint was found to be Amazon. However overall, technology and telecommunications companies were seen as the largest target as they were had the highest Darknet Index scores, indicating that they are the most attractive firms targeted by threat actors.

PRIVACY, ETHICS, AND THE DARK WEB

Richard (2018) defines privacy as a state in which an individual is able to hide information about themselves for no reason other than to keep it from others. When you lack online privacy, he says, it means that all your information can be accessed, either willingly or forcibly. Anonymity, on the other hand, is the ability to hide one's true identity from others, chiefly to remain unknown without hiding or censoring their activities. Richard asserts that while anonymity might not be as inherent as privacy, it is just as important in any society, because it enables activists and whistleblowers to say what many would otherwise not say for fear of retribution. Hence, he believes that the anonymity provided by the Dark Web provides activists with a measure of protection from powerful corporate and political enemies. Without it, he says, few would be willing to come forward.

The University of Warwick and TNO (2017) provide arguments that are sympathetic with those presented by Richard. They note that technology commentators and researchers routinely predict that web activity will increasingly migrate to the Dark Web as people become more concerned about their privacy and less tolerant of corporate monitoring of their behavior for marketing purposes. Privacy and censorship concerns, they say, are emerging as significant predictors of reduced opposition to the Dark Web where anonymity helps to protect one's privacy.

The University of Warwick and TNO believe that people's Dark Web activities are not only innocuous, but they also constitute the exercise of their valuable freedoms. Chief amongst these, they say, are the freedom to express political views or sexual preferences without fear of persecution by authoritarian regimes and the freedom to exchange information without manipulation or monitoring by profit-seeking companies. The authors contend that some Dark Web users consider the term 'dark net' or 'Dark Web' itself a media fabrication to draw attention away from the legitimate, innocuous, and even life-saving use of the Dark Web and towards those that are criminal. Some, they say, like Edward Snowden and Julian Assange, see government-sponsored attempts to crack anonymity on the Dark Web as an attack on freedoms, especially privacy.

The University of Warwick and TNO suggest that a law enforcement approach to the Dark Web that treats all activity there as suspect in an undifferentiated, blanket manner risks undermining the exercise of these freedoms. They contend, for example, that attempting to crack encryption and expose the iden-

tities of individuals interacting anonymously on the Dark Web might not only expose those particular individuals to harm from authoritarian governments, but also undermine the trust that is vital to the effective function of the Dark Web as a space safe from political persecution. For this reason, they suggest that law enforcement organizations in liberal democratic jurisdictions adopt a targeted approach to policing the Dark Web, focusing on exposing, disrupting and prosecuting criminals while refraining from interfering with innocuous activities and the exercise of political freedoms.

ETHICAL THEORIES

Ethical theories can be useful in helping to articulate people's judgments when they examine the morality of the activities of the Dark Web and means for intervening to constrain controversial behavior. Ethical theories provide a foundation for a reasoned moral argument and they provide a basis for legitimacy since they are rooted in ethical philosophy.

Sound ethical theories share a common property. They enable an individual to make persuasive, logical, and reasoned arguments based on the principles stated by the ethical theory. To illustrate this, two ethical theories, Kantianism and Utilitarianism, will be briefly described and then used to see how an ethical argument about the Dark Web might be framed.

Kantianism

Kantian ethics, originating with the German philosopher Immanuel Kant (1724-1804), is an ethical theory concerned about not what we do, but what we ought to do -- our dutifulness. Dutifulness reflects good will, which is the desire to do things right based upon rules that everyone ought to follow. That is, a dutiful person acts the way they do because of a moral rule. Moral rules are imperatives that are either hypothetical or categorical and they are the means by which reason commands our will and our actions. Hypothetical imperatives equate to conditional if, then statements relative to what you are trying to accomplish. Categorical imperatives command unconditionally as they are unequivocal. For Kant, rules are paramount. Everyone is held to the same standard and there are clear guidelines for appropriate behavior. Hence, in Kantianism it is not the outcome of a behavior that matters. It is the intent, the rule behind the action, that is most critical (California State University Sacramento, 2016).

One Kantian categorical imperative states that one should always respect the autonomy of other people, treating them as ends in themselves and never only as means to an end. With the Dark Web, this would be a difficult case to make. Since some activity on the Dark Web routinely involves compromising a target's privacy without their consent, these Dark Web participants are not respecting the autonomy of people and they are in fact using others personal data as a means to an end to further their own self-interest. Moreover, because they engage in their Dark Web activity anonymously, one could also judge this to be problematic. With Kantianism, you want everyone to act as you want all people to act towards all other people. In the Dark Web instance, where everyone is anonymous and thereby compromising the transparency of sources, there is no opportunity for anyone to value a source and hence to trust their intentions. Overall then, the intent to hide one's identity from others is not something which one would want to apply universally to every situation. However, there are exceptions such as the instances where whistleblowers require concealment with their intent to act in the common good. Here the morality of

these Dark Web activities might be justified through the use of a Kantian hypothetical imperative. That is, if the intent of the use of anonymity by a whistleblower is to afford the expression of information that promotes the common good, while also protecting them from oppression and harm, one could state this is morally justified.

Utilitarianism

Unlike Kantianism, Utilitarianism [originating from Jeremy Bentham (1748-1832) and John Stuart Mill (1806-1873)] examines right or wrong based on the consequences of an act or a rule. The act utilitarian perspective applies the principle of utility to individual moral actions and the rule utilitarian applies the principle of utility to moral rules. The right act is one that produces the greatest happiness for a community or society. A wrong act decreases the total happiness of the affected parties. The right moral rule of conduct is one where if it is adopted by everyone, will lead to the greatest net increase in happiness for all involved. Hence, in the utilitarianism ethical perspective, one must calculate what action or rule achieves the best results. That is, one must account for and weigh the good and the bad elements affecting a situation to determine the net consequences of the action or rule. Unlike the Kantian perspective where the focus is upon examining the will that motivates action, it is the “happiness” or the maximum well-being outcome that is most critical in Utilitarianism (Cavalier, 2002).

Applying the Utilitarian perspective can be fraught with complications. It requires that acts and rules be assessed using a utilitarian calculus where the good and bad of the Dark Web would be weighed on a scale. From an Act Utilitarian perspective, for example, one would have to quantify the plusses and minuses of Dark Web consequences relative to such factors as the intensity of the experience, its duration, the financial consequences of the action(s), the number of people positively and negatively impacted, and the potential of this activity and/or entity to produce more experiences of the same kind. To decide whether the action of Dark Web actors is right or wrong, one must total the positive and negative consequences to all of those being affected and choose the alternative with the highest total score.

The major potential drawback of this approach may be the potential ambiguity and biases inherent in trying to identify and quantify both the pros and cons of Dark Web activity and behavior. Trying to reach consensus as to the intent and impact of the Dark Web can be problematic since the costs and benefits in the analysis would have to be quantified to a common economic unit of analysis. And in doing the assessment, bias may be made manifest via selectivity in what data is selected and how it is weighted.

That said, the principles of Utilitarianism are typically applied in assessing the impact of the Dark Web. Where Kantianism might confine us to assessing the intent of a Dark Web actor on a case by case basis, Utilitarianism provides a basis for enabling a calculation that expresses a judgement of the overall consequences of Dark Web activity on the public, which then can be used to justify the value (and the expense) of the government legislation and the cybersecurity measures that are implemented to protect citizenry and their privacy from Dark Web activity.

SOLUTIONS AND RECOMMENDATIONS

Privacy is a something that people intrinsically want to protect. Ethics provides moral justification for explaining why. The Dark Web challenges both. It is a frontier not unlike the Wild West.

Ethical theories such as Kantianism and Utilitarianism, help us to understand and articulate the moral issues inherent in both the intent and the consequences of the illicit behavior being manifested on the Dark Web. And clearly, there real data privacy issues that have had moral, legal, and economic consequences. At the same time however, there are also innocuous and even positive behaviors that occur in the Deep Web space.

Hence it is important going forward to monitor the ethical and social consequences that the distribution of anonymous browsers and the widespread availability of open networks create. While there is extensive interest now in our cybersecurity, we should also stay cognizant of the fact that some of the activities of the Dark Web may have a positive effect on societal behavior. Clearly hacking is an activity with no moral justification. The goodness of whistleblowing, however, is not so easy to assess. From the perspective of Kantianism, one must assess the goodness of the whistleblower's intentions. And Utilitarianism demands that we systematically evaluate whether the impact of the whistleblowing was positive or negative for the majority of the citizens who were targeted by its action.

Unfortunately, most of us only consider the ethics of a situation when we have been made aware that there is a problem. Typically, we are too trusting that somehow online entities will respect our data privacy. Sometimes we are simply too ignorant of potential threats or too busy to manage our online activities with due diligence.

Government rules mandating strict data management policies were therefore probably inevitable. The idea that firms will self-regulate has been shown not to work well. There was and is a gold mine of online data for firms to harvest and analytics can tell them more about people's behavior than they ever knew to ask. In the process of doing this, the deliberate or unintentional misuse of personal data became inescapable. New privacy laws are a clear admission that something has been wrong and that individuals are basically powerless to control how their private information is shared.

To expect consistent ethical behavior online has been shown to be wishful thinking. In fact, with the Dark Web, ethical behavior is seen by many to be an oxymoron. Eventually, the future of the Dark Web may depend how much society will tolerate anonymous, unregulated free speech. Hence, it is probably prudent that we should monitor current and future Internet regulations. I think it is important to recognize when legislation may be compromising the actions of those with good intentions when its actions are trying to fix behaviors that it judges to be morally wrong.

FUTURE RESEARCH DIRECTIONS

As we move forward, we must be highly attentive to how we deal with the Dark Web. What we do to it and how we do it will tell us as much about ourselves as about it. If we work to aggressively stamp out all criminal behavior, we might inadvertently silence important voices that needed this platform's anonymity for safety from oppressors. It is a balancing act that will require careful thought and reflection as we are actively trying to attend to our cybersecurity. What ethics tells us is that we should stop to consider whether using a scalpel would be better than using a hatchet when dealing with Dark Web issues and it will help us to understand why. Ongoing research will be needed to document and explore the arguments that will be voiced. In doing so, we can examine whether these judgements are grounded in the reasoned moral arguments of ethical theory.

INTRODUCTION

Ever since its conceptualisation, the Internet has revolutionised the way people live. From faster communication to convenient information sharing, the human race has been abundantly blessed by the applications of the Internet. Most people today, mainly use the Internet for accessing various websites or web pages containing different forms of information – like text, image, audio, video etc. Such widespread use of the Internet for data retrieval purpose, has got people thinking about the difference between the Internet and the World Wide Web (or simply the Web). In essence, the Internet comprises of networks across the world, interconnected together to form one massive global network. These networks are connected via cables or satellite links and follow a predefined set of rules for communication, called protocols. The Internet uses different protocols to deliver a variety of services to its users – like data dissemination, email, file sharing, online messaging etc. Out of all such services the World Wide Web only provides data dissemination or information sharing capability to the Internet. It allows web pages to display content present on world's different networks by using Hyper Text Transfer Protocol (HTTP). Services like email and file sharing, which are not a part of the World Wide Web, are governed by Simple Mail Transfer Protocol (SMTP), Post Office Protocol (POP) and File Transfer Protocol (FTP) respectively. Since users mostly access the Web portion of the Internet to share and/or retrieve information, the two terms – the Web and the Internet - are used interchangeably by common people. But these two terms are not synonymous. The Internet is the underlying (hardware) infrastructure over which the World Wide Web (software) hosts digital content in the form of websites or simply web pages.

SURFACE WEB

The Web provides its users with billions of web pages that can be easily accessed via standard web browsers and search engines. This part of the Web which is openly available to everyone is known as the Surface Web (Santos, 2015). Users access online resources present on Surface Web by either typing

DOI: 10.4018/978-1-5225-9715-5.ch010

a Uniform Resource Locator (URL) in the web browser or submitting a string of keyword(s) to query the search engine. The latter option provides them with an ordered list of search results that are most relevant to their search query. Both these methods allow quick and easy access to information on the Surface Web - also known as Visible Web or Clearnet. With huge amounts of information lying just a few clicks away, the general audience tends to think that all online content hosted on the World Wide Web is part of the Surface Web and can be accessed by them through conventional search engines (like Google and Bing) and web browsers. But this is far from the truth. The Surface Web contains less than 20 percent of the total information present on the Web (Santos, 2015) (Sui, Caverlee, and Rudesill, 2015). This is because the Visible Web is solely formed by the contents that search engines are able to reach on the Web. Any web resource that is beyond the reach of search engines, is not a part of the Visible Web. Thus the volume of content present on the Surface Web is limited by the techniques that search engines follow to extract information from the World Wide Web.

Search engines make use of application programs that scan the World Wide Web to create an index of all “reachable” web resources. These programs are known as crawlers/spiders/harvesters. Crawlers navigate the Web to gather documents and files present online in the form of web pages. Usually, web pages are linked to each other via incoming and outgoing hyperlinks. These hyperlinks enable search engines’ spiders to reach different web pages and extract information from them. This process of gathering information while moving from one web page to another through hyperlinks, is known as crawling. Beginning with an initial set of seed URLs, a crawler scans every web page linked to these URLs via outgoing hyperlinks (Santos, 2015). All online content that is reachable via incoming and/or outgoing hyperlinks gets crawled. The crawled pages are then indexed to allow easy retrieval for later purposes. Finally, when the user submits a search query, the search engines display these indexed web pages in an ordered manner.

Though search engines have made a lot of information available, but a very large portion of the Web still remains inaccessible to users. This is because web spiders can only enter and leave web pages via hyperlinks. Web pages which do not have incoming hyperlinks cannot be reached by crawlers. Such pages remain un-crawled and their content remains hidden from the eyes of search engines’ spiders. This is why the number of web pages on the Surface Web is a subset of web pages available on the World Wide Web. The Web is an ocean of knowledge and crawlers dive into it to gather as much content as possible. Contents gathered by crawlers form the Surface Web while the remaining contents form a separate layer of the Web, called the Deep Web.

DEEP WEB

The World Wide Web is a collection of enormous data both accessible directly and not accessible directly through crawlers. The accessible data, which is indexed by standard search engines, forms the visible tip of the iceberg whose major portion lies unseen in the deeper layers of the Web. This “unseen” portion of the Web which cannot be indexed by traditional search engines is referred to as the Deep Web. It consists of all those contents that cannot be crawled by search engines’ spiders and hence does not appear in search results. Though Deep Web content remains hidden from regular searches, it is not usually illegal or dangerous, it is just made to be unsearchable. Most of this information can be displayed as a result of a targeted search over the Web. Deep Web, popularly known as the Hidden Web or Invisible Web,

contains a variety of information including academic records, conference proceedings, legal documents, medical data, corporate data, scientific findings, database contents, confidential citizen data protected by governments, information present in universities' library websites and any online information that is accessible only by registered individuals. This type of Deep Web data is generally found in:

- **Unlinked Web Content:** Any web page that is not linked with other web pages through backlinks (incoming and/or outgoing hyperlinks) remains veiled and it only becomes visible if the exact URL is known.
- **Dynamic content:** Websites that provide users with search boxes (instead of hyperlinks) to navigate among pages of a website, become a part of Deep Web. This category also includes information that is made accessible only after user fills an online form.
- **Private Content:** Deep Web also includes contents present on websites and networks, owned by governments, educational institutions and private organisations, that require registration and login to be accessed (Norton, 2016). For example, accounts created by users on online social networking websites, bank websites and even e-commerce sites are not returned in results of search engines.
- **Paid Services:** Another kind of un-crawled content includes paid services that are made available to authorised individuals only (Cooper and Chikada, 2015). For example: Paid video-streaming platforms.
- **Limited Access Websites/Web Pages:** All online material that requires human verification (like CAPTCHAs) before being displayed, remains unindexed and hidden from Surface Web (Santos, 2015).
- **Restrictions by Website Developers:** Web spiders (crawlers) can be prohibited from crawling a website if appropriate settings are made in the associated robots.txt file (Santos, 2015).
- **Limited-Access Networks:** This covers all those resources and services that are not reachable with standard network configurations. For example: sites with domain names that have been registered on DNS roots that aren't managed by the ICANN and have URLs with nonstandard top-level domains. Such sites usually require a specific DNS server to resolve their URL. Other examples are sites that registered their domain name on a completely different system than the standard DNS, like the .bit domains (Ciancaglini, Balduzzi, McArdle, and Rösler, 2015).

So Deep Web is that place on the World Wide Web which cannot be accessed via search engines' keyword search but can be reached by entering the exact destination URL in any conventional web browser. Although it is almost infeasible to accurately predict the size of this Invisible Web, it is estimated to be 400-500 times larger than the Surface Web. Since Deep Web content is not displayed to everyone in search engine results, this part of the Web offers a higher level of privacy as compared to Visible Web pages. However, Deep Web websites are still under the authority of Internet Service Providers that provide private server hosting services. While they ensure privacy, they are far from being anonymous (Norton, 2016). Anonymity on the Web is offered by a different segment of the Web, known as the Dark Web.

DARK WEB

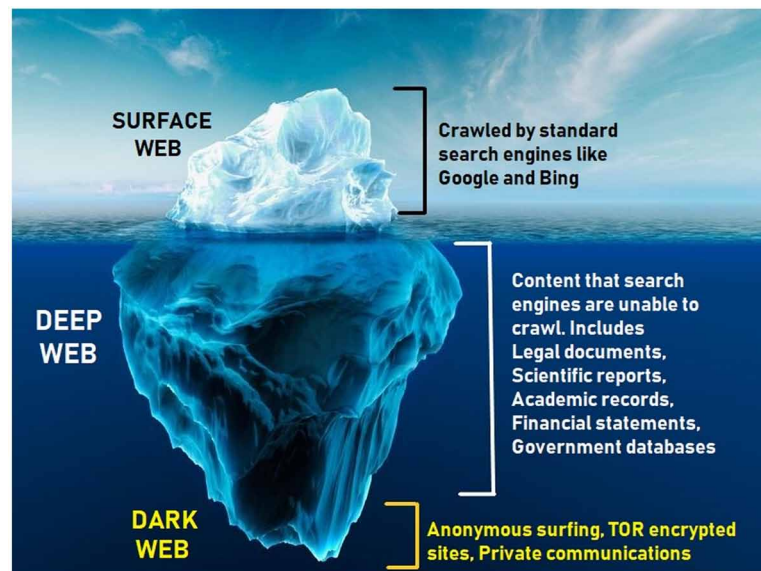

The segregation of the Web into Visible and Invisible Web has been caused by present-day search engines which can crawl only hyperlinked content. Though data on the Invisible Web remains hidden, this layer of the Web was never purposely created to conceal information. Rather, there exists another part

of the World Wide Web which was specifically developed with the aim of hiding every activity taking place on it. This is known as the Dark Web. Many people lack a clear understanding of these two layers of the Web: Dark Web and Deep Web. Some people assume Dark Web is same as the Deep Web, while others claim that these are two disjoint layers. Both these statements are incorrect. The Dark Web is a subset of the Deep Web. Like the Deep Web, Dark Web also remains unindexed by search engines but unlike Deep Web, it cannot be reached through standard web browsers. Dark Web requires specialized softwares, specific configurations and authorizations to be accessed (Dange, Malkan, and Jha, 2018). Figure 1 depicts these 3 layers of the World Wide Web in the form of an iceberg.

Another important difference includes the stability of websites/web pages hosted on Invisible Web and Dark Web. While sites on Surface Web and Deep Web are usually stable and stay up for long durations of time, websites on the Dark Web tend to have a shorter life span as compared to Clearnet websites. A survey of Dark Web was conducted by *Securelist* and it was found that most of the sites on this part of the Web are quite unstable. While most Dark websites were found to be active for a duration between 200-300 days, there were many sites that were only live for around 60 days (Intelliagg, 2016). Even with these characteristics, the popularity of the sites on the Dark Web has been on the rise.

Though the Dark Web has existed for years, one incident that brought it into limelight was the hacking of Ashley Madison database in 2015. Ashley Madison is an online dating platform for married people. During July 2015, hackers were able to access its database containing personal details of around 37 million customers. Around 9 GB of this data, including clients' names, addresses, emails, sexual preferences and credit card information, was dumped on Dark Web (Weimann, 2016). This incident drew major public attention and gave a boost to the popularity of this part of the World Wide Web. If we compare the World Wide Web to an ocean, the Visible Web are the waves present on the surface. Below the surface, lies the invisible world of the Deep Web. And the deepest part of this Invisible Web, requiring highly specific tools and equipment to reach, is the Dark Web. TOR is one such tool that opens the doors to the world of Dark Web.

Figure 1. Different parts of the World Wide Web are displayed as different portions of the iceberg

TOR: GATEWAY TO THE DARK WEB

Navigating websites on the Dark Web is becoming increasingly convenient as new software enter the markets every day. These software offer anonymising and encrypting facilities to access Dark Web websites. TOR is one such software that has been the most popular candidate in this category. TOR is an acronym for “The Onion Router”. It is a free software that allows anonymous communication over the Web. People often use the acronym TOR to refer to both the TOR network as well as the TOR browser. While the TOR network is a collection of a large number of volunteer computers that run a specific server application, the TOR browser allows users to hide their identities when accessing the content hosted on the TOR network (Poobalan, 2018). In essence, the TOR browser is used to access the TOR network. Its sole purpose is to conceal users’ browsing patterns, preferences, location as well as their actual identities in the Internet space. Thus TOR allows its users and their online activities to remain untraceable (Cooper and Chikada, 2015).

At present, TOR is a non-profit project which includes maintenance of the software as well as the network. It is run by people who actively strive for users’ right to online privacy and anonymity. Even with its expanding user base, TOR strives to remain non-profit and never collects user data (Poobalan, 2018). This has deepened the trust of its audience and made it famous in the Dark Web community. With a total of 17.5 million downloads recorded till date, the TOR project claims to have around 2 million daily users. Though most of these users find TOR services to be slower than connections made on the Surface Web, they are ready to pay this price for the services it offers. TOR’s slow speed is a result of its anonymizing technology, called Onion Routing. This technique was developed by the U.S Navy back in 1990s so as to safeguard its online intelligence communication (Poobalan, 2018).

To preserve user anonymity, TOR encrypts its traffic several times. This encrypted traffic is then directed through multiple TOR servers that are a part of the TOR network. These servers (sometimes referred to as relays/routers) are always selected randomly during connection establishment in order to create a private and secure communication pathway. At each relay node, one layer of encryption is removed so that the current node can discover the address of the next destination node. This is similar to peeling an onion, layer by layer, such that every relay can only peel the topmost layer. Hence the name the Onion Router. Onion Routing gives rise to an encrypted connection that is built step by step between every two nodes, such that each node only knows from which node it received data packets and to which node the received packets must be forwarded. This prevents tracing the source and destination of any user request. This way the TOR network allows its users to hide their online footprints and escape surveillance.

TOR is one way to enter and sail through the Dark Web. Other well-known alternatives include I2P (Invisible Internet Protocol) and Freenet. While I2P provides anonymity between applications via encrypted connections, Freenet utilises peer-to-peer facilities to establish a fresh path for every new connection. Though this makes reopening of pages slower, Freenet is considered simpler and more convenient by the end users. With many such anonymization software available online, it is becoming easier to be a visitor as well as a host on the Dark Web. This has allowed different kinds of users to access and host a variety of illegitimate and legitimate services on the Dark Web.

ILLEGITIMATE ACTIVITIES ON THE DARK WEB

1

The Dark Web allows its users to anonymously access its websites through the use of software like TOR. This way they are able to escape surveillance and their identities, preferences, locations and online activities also remain hidden. Though online anonymity paves way for user privacy, it also opens doors to a plethora of criminal activities. In recent times a large number of websites have come up on the Dark Web that provide illegitimate goods and services. Some of these are:

1. Counterfeit Currency

The Dark Web acts as the distributor of counterfeit currency which is sold with a guarantee of surpassing standard ultraviolet light checks successfully. Money to be paid in such cases varies with the quality, quantity and the type of currency being falsified. For example: Six hundred dollars can fetch around twenty five hundred dollars in counterfeit U.S. notes (Dange, Malkan, and Jha, 2018).

2. Forged Documents

Several sites on the Dark Web are also famous for providing fake passports, immigration papers, driving licences and other identity documents for any country in the world (Ciancaglini, Balduzzi, McArdle, and Rösler, 2015). The price of these documents mainly depends upon the country in which they will be used. These services allow notorious people to acquire fake citizenship as per their needs. Other forged documents that are readily available include citizenship papers, fake IDs, college diplomas and even diplomatic identity cards.

3. Drugs

Different types and quality of illicit drugs can be purchased on the Dark Web. Even banned drugs and pharmaceutical products like Ritalin and Xanax also find a place on Dark Web marketplaces (Ciancaglini, Balduzzi, McArdle, and Rösler, 2015). Silk Road is an example of a Dark Web marketplace which became famous for the wide range of drugs that were sold through it in huge amounts.

4. Stolen Confidential Information

This includes buying and selling of stolen credit card details, bank account details and even personal information like social security numbers. Apart from physical credit or debit cards, bank accounts can also be purchased at different prices in this Dark world.

5. Hackers

Another community that benefits from the Dark Web, includes hackers. They can easily buy sophisticated malwares and even get paid by interested parties to carry out any kind of online hacking attacks against specific governments, organisations or individuals (Spalevic and Ilic, 2017).

6. Arms and Ammunitions

Illegal trade of explosives, weapons and firearms is also carried out openly. These services ensure that the requested goods are delivered to the buyer in special packaging that can easily cross any kind of scanning and security checks. Sometimes, arms and ammunitions are stuffed in children's toys or electrical equipment to evade the eyes of authorities (Dange, Malkan, and Jha, 2018).

7. Hitmen

Many portals on the Dark Web allow people to hire professional assassins. Often the hiring party has the option of specifying how they want their enemy/opponent to be murdered – using regular methods or through bombing, torture, rape etc. Money demanded for such acts varies with the selected murder method and the social status of the victim (Spalevic and Ilic, 2017).

8. Human Organ Trafficking

Human organ trafficking is another business which has its roots deeply penetrated in the Dark Web. Kidneys, liver, heart and eyeballs are examples of frequently bought organs in these black markets (Dange, Malkan, and Jha, 2018).

9. Terrorist Activities

The anonymity of this part of the Web has given a huge boost to major terrorist groups across the world. From secret communication and propaganda to recruitment and training, everything that cannot be openly done on the Visible Web, is carried out through Dark Web (Sui, Caverlee, and Rudesill, 2015) ; (Weimann, 2016).

10. Child Pornography

The Dark Web has also become a famous destination for hosting child abuse videos as well as child pornography. Though the Visible Web also faces the problem of illegal hosting of such videos, but this problem is much graver in this dark underground world. In 2012, the Federal Bureau of Investigation (FBI) launched “Operation Torpedo” against the users of three Dark Web websites that hosted child pornographic videos (Sui, Caverlee, and Rudesill, 2015). This highlights the intensity of this problem.

The list of illicit activities carried out using Dark Web is endless. Criminals thrive in this secret world because procedures to trace their footprints are complex and tracking them is next to impossible. A key factor responsible for the growth of Dark Web based crimes is the use of Bitcoin like cryptocurrencies as a mode of payment.

USE OF BITCOIN ON DARK WEB PLATFORMS

Cryptocurrencies are digital currencies that are secured using cryptography methods. Most financial transactions on the Dark Web are carried out through digital currencies like Bitcoin. This is a preferable method of payment because cryptocurrencies ensure the anonymity of the transaction – not only

the amount of money exchanged but also the identities of the involved parties. Together with browsers like TOR and I2P, cryptocurrencies offer a dual layer of obscurity to the Dark Web domain. This allows notorious people to trade Bitcoins for anything they want on the Dark Web without getting noticed by the legal authorities. Users who wish to trade through Bitcoin, must maintain a Bitcoin wallet (called the dark wallet when used on Dark Web) either on their own or through third parties (Piazza, 2016). There is also a provision of obtaining special credit cards if the Bitcoin wallet owner wants to cash his Bitcoins. The websites offering such cards assure its users that the source of their transactions shall remain masked. Many websites on the Dark Web use Bitcoin as the sole medium of transaction. Silk Road was an example of one such site.

SILK ROAD

Silk Road was an online marketplace on the Dark Web. It was developed, owned and operated by a young programmer named Ross William Ulbricht. To hide his actual identity, Ross operated with the administrator name “Dread Pirate Roberts”. Silk Road started its operations in 2011 and carved a niche for itself with its highly professional website. In a small period of 3 years, the popularity of this site went up as more and more drugs were listed and made available through it (Bhaskar, Linacre, and Machin, 2017). Services like computer hacking, selling of forged passports, driver’s licences, credit cards and identity documents like Social Security Numbers were also provided on this platform. Apart from this, the website also hosted a community forum that offered suggestions on how to avoid the eyes of law enforcement by transacting safely on the platform. Silk Road, which was accessible only through the TOR network, accepted its payment only in Bitcoins. In the time period between February 2011 and July 2013, around 1.2 million transactions were recorded on this website from almost 3,877 unique seller accounts and 147,000 unique buyer accounts. This helped Ulbricht to build a massive empire worth \$ 1.2 billion in such a limited time. In one of the interviews given by Ulbricht to Forbes magazine, he claimed that he would never be caught. But Silk Road’s journey concluded with the arrest of Ulbricht inside the San Francisco Public Library followed by shut down of Silk Road in 2013 (Poobalan, 2018). Ulbricht was found guilty and received life imprisonment without any chance of parole. The severity of this punishment was due to charges against him that included money laundering, computer hacking and conspiracy to traffic narcotics through internet. Ulbricht’s case made headlines and led to a boost in the popularity of the Dark Web among common people. A month after Ulbricht’s arrest and shutdown of Silk Road, it was started again by Blake Benthall. This time the business boomed for a year, before its owner Blake Benthall was arrested and the website was shut down again. An hour later the portal was revived again. Just like its predecessors, Silk Road 3.0 is like any normal e-commerce platform but with “not-so-normal” listings.

According to (Dange, Malkan, and Jha, 2018) the value of Bitcoin was directly affected by the growth of Silk Road. Bitcoin tripled in value just a month after Ulbricht founded Silk Road. This sudden hike in price drew attention of investigators and as they started exploring the causes, Bitcoin lost about 90% of its value. Though Silk Road was eventually shut down, but this was not an easy task for law enforcement authorities. One factor that added to its difficulty was the use of Bitcoins for conducting transactions. The use of digital currencies did not remain limited to Silk Road. Most black markets now use Bitcoin as a preferred mode of payment. To deal with this upsurge in Bitcoin financed cyber crimes, law enforcement authorities have started taking strict actions against the owners/administrators of many famous Dark web portals.

CURBING CRIME ON DARK WEB

As cyber criminals devise new ways to exploit the anonymity offered by the Dark Web, law enforcement agencies across the globe are also developing new strategies to deal with them. Although Bitcoin and TOR wrap the world of Dark Web in double layers of anonymity, but these layers are just as strong as their weakest point. Even if Bitcoin transactions do not carry any personally identifiable information, there are several other ways of nabbing Dark Web criminals. For instance, drugs purchased online are eventually delivered to a geographic location via the postal system. This can give a major lead to the investigators who aim to catch potential suspects. Another activity that quickly draws the attention of law enforcement, is the conversion of large amounts of Bitcoin to fiat currency. An example of this was a police raid in Netherlands that led to the arrest of ten men who were caught encashing Bitcoins and withdrawing millions from ATMs (Bohannon, 2016).

But incidents like these do not happen often, so law enforcement agencies along with the research community has started focusing its attention towards analysing the patterns of Bitcoin transactions to uncover notorious participants of Dark Web platforms. Continuous monitoring and data collection of Dark Web's transactions can help to identify Bitcoin addresses that belong to the same person/group if they are used as input in the same transaction. In (Reid and Harrigan, 2013) the authors proposed to use Directed Acyclic Graphs to represent the flow of Bitcoins between users and transactions to highlight interesting patterns of user activity. Clustering algorithms based on unsupervised machine learning can also help to isolate Bitcoin addresses with multiple incoming transactions as belonging to online vendors hidden in the Dark Web marketplace. In addition to this, if investigators get access to suspected Bitcoin wallets, important information about the owner's identity and past transactions can be easily revealed through the associated "wallet.dat" file (Turner and Irwin, 2018).

Though analyses of Bitcoin addresses can expose significant information, but generally multiple addresses are linked to each wallet and Bitcoin owners tend to use different addresses for each transaction to increase anonymity. This is a severe obstruction while clustering Bitcoin transactions and tying them to physical identities. To increase the problem, Bitcoin mixing services are also offered on the Dark Web that aim to break the money trail and weaken the link between transactions and Bitcoin wallet owners (Wegberg, Oerlemans, and Deventer, 2018). So investigators have now shifted their attention towards methods that map Dark Web's financial transactions to their source and destination IP addresses. In an effort to establish such a mapping, Philip and Diana Koshy developed software similar to the one used by Bitcoin vendors and buyers to interact with Bitcoin blockchain. The financial transactions of everyone interacting through this software was accessible by the Koshys. The couple noticed patterns in the number of transactions being sent out by certain IP addresses and were able to map around 1000 Bitcoin addresses to their corresponding IP addresses (Bohannon, 2016). Such IP tracing methods offer significant advantage in de-anonymising cyber criminals that mask behind Dark Web and can be seen as a first step towards breaking the anonymity offered by TOR. But many times even these techniques are not enough.

Sometimes the investigators themselves have to get their hands dirty to clean the Dark Web. There have been instances when law enforcement personal had to pose as vendors/buyers of illegal weapons and drugs on Dark platforms in order to entice cyber criminal and catch them in the act. When such tactics failed to meet their purpose, investigators have to level up their game by using "network investigative techniques" to catch suspects. This surveillance method remotely installs malware on a suspect's computer and helps investigators to follow the suspect's activities on the Dark Web without accessing his/her device physically (Ghappour, 2017). The level of anonymity that Dark Web has developed, is not

easy to infiltrate and there have been instances where cyber criminals who have been caught by their own negligence. It was Robert Ulbricht communication on a public forum where he advertised Silk Road, that eventually busted him (Ghappour, 2017). After all, to err is human! Though law enforcement tries its best to curb the use of Dark Web, there exists a legitimate side to this world as well.

LEGITIMATE USES OF THE DARK WEB

There is no doubt that the Dark Web has become a hotbed of cybercrime that is funded by cryptocurrencies. But originally it was not developed for this purpose. There were noble intentions behind its development. And even today, there are many Dark Web users who are not involved in any illicit activity and use this Web for legit purposes. These people utilise the anonymity of the Dark Web to bring about a positive change. Common examples include:

- People living in countries under suppressive regulations, often use the anonymity of the Dark Web to convey their ideas and thoughts. Revolutionary ideas in such regions are often toned down and that's why individuals or even groups try to communicate with public through Dark Web platforms. For example, Facebook launched a version of its website on TOR network to provide its services to users who live in countries that ban the use of Facebook. This version which can be accessed at <https://facebookcorewwi.onion/> allows people to communicate with each other at higher levels of protection against surveillance.
- Journalists and whistleblowers also utilise the Dark Web to reveal information that should be brought to the notice of the common man, but remains veiled. They use the Dark Web to anonymously highlight important information and incidents without fearing political surveillance and suppression. In 2010, TOR was given an award for Projects of Social Benefit from the Free Software Foundation for helping whistleblowers and supporters of human rights (Sui, Caverlee, and Rudesill, 2015).
- Bloggers, writers and other creative people who fear censorship on the Surface Web, become frequent users of the Dark Web.
- Celebrities and common people who do not want to leave behind any kind of online trail including their identity, search history or location, are active users of the Dark Web.
- Researchers, students and teachers who want to access vast resources of knowledge available on the Dark Web, also access this part of the Web for legitimate purpose. Many scientific findings that have not been made public on the Surface Web, can be easily found on the Dark Web (Dange, Malkan, and Jha, 2018).

Such people look upon Dark Web as a haven that offers anonymity, freedom of speech and privacy. Though this aspect of Dark Web is rarely highlighted, this was the sole reason behind its development.

CONCLUSION

The Dark Web is that part of the World Wide Web which is neither crawled by conventional search engines nor accessible through traditional web browsers via URLs. It requires the use of specific software and configurations to enter and sail through this part of the Web. A lot of time and patience is also

needed to explore the Dark Web content. But users tend to pay this price in exchange of their privacy in this digital underground world. This need for privacy draws the attention of people who do not want to be tracked while surfing the Web but cannot find a way for the same on the Surface Web. The Dark Web looks like a lucrative option to them. But Dark Web's anonymity is a double edged sword – it all depends how one uses it. People who seek online anonymity come from different corners of the world, with different intentions in their mind. When used in a benevolent manner, Dark Web can serve as a medium to ensure user's online privacy. But with malevolent intentions, it can become a playground for criminals. Therefore, like every other invention, the Dark Web has its own set of pros and cons. It can prove to be very useful or disastrous depending upon its application. The manner in which it is utilised, ultimately decides whether Dark Web is a boon or a bane.

KEY TERMS AND DEFINITIONS

Bitcoin: It is a kind of digital cryptocurrency that is used for transactions in many black markets of the dark web.

Crawling: It is the process by which search engines gather online information through crawling robots by moving from one web page to another by the use of hyperlinks.

Dark Web: The part of world wide web that allows its users to remain anonymous by the use of specialised software to mask their online presence.

Deep Web: The part of the world wide web that cannot be crawled by web crawlers and does not appear in results displayed by search engines.

Indexing: The process followed by search engines to create an index of the contents present on the Internet, to allow easy retrieval when displaying results to user queries.

Internet: It consists of networks across the world, interconnected together to form one massive global network.

The Onion Router (TOR): It is a free and open source software that allows anonymous communication over the dark web.

Surface Web: It is the part of the world wide web that can be easily accessed by everyone through the use of standard web browsers and search engines. It is also known as clearnet or visible web.

World Wide Web (WWW): It provides information sharing capability to the Internet through web pages that are hosted online using hyper text transfer protocol (HTTP).

File-Sharing and the Darknet

INTRODUCTION

The public interest in free information exchange is considerable. Besides textual information, this includes multimedia content, data sets and software as well. Compared to text data, the latter require the transfer of huge data volumes, which cannot be handled via Email, forums or chats. In part, the Internet is also rooted in this interest. (Nelson et al., 1981) addressed the global exchange of research results as early as 1960 in the Xanadu project.

However, the free exchange of information can also be misused for illegal measures, including copyright violations, the distribution of child pornography, illegal propaganda or instructions for building explosives. The degree of stigmatization for these use cases varies largely. Large parts of the Internet community has always supported the uncontrolled distribution of copyrighted material. This has led to a constant battle between copyright holders and file sharing activists, with technological advances on both sides. The automated crawling of IP addresses by file sharing peers was answered by obfuscation measures, which can be seen as first approaches to privacy networks. Legal discussions about the impact of file sharing for copyrights were initiated as well (Wood, 2009).

These networks allowed distributing arbitrary file types, often arguing with privacy and the risk of censorship in more public file distribution networks and mentioning documents with political backgrounds as the typical data to be shared. However, they were also utilized for the file sharing of mp3s and movies. Child pornography is reported to be commonly shared via such protected networks as well.

Privacy networks and the file sharing in it are typical examples of a dual use, but this work will not be discussing the pros and cons. Every side will find arguments either for supporting or prohibiting this technology. In addition, the legal aspects of file sharing and copyright differ depending on the country. Our aim is to show which role file sharing and the growing need for privacy within it played in the development of privacy networks and how to achieve privacy in file sharing networks today.

BACKGROUND

With increasing download speeds and the general growth of the Internet, sharing content over the Internet became more and more common. Even before the world wide web was introduced, mailing lists and FTP servers were used to access illegal copies of photos, documents or (with the rise of mp3) songs. The first file sharing methods were still centralized and depended on a server. Law enforcement or administrators could easily attack these servers. This led to the adoption of alternative infrastructures, the peer-to-peer networks. File sharing via peer-to-peer networks has been used for the exchange and distribution of copyrighted material since the advance of this technology.

DOI: 10.4018/978-1-5225-9715-5.ch011

This section discusses the history of illegal content distributed via the Internet, commonly called 'warez', and first general approaches to distributed warez without being monitored and sued.

Bulletin Boards

The concept of warez existed even before the Internet as we know it today. The book NO COPY reports from the origins of today's warez scene (Kroemer & Sen, 2006). In the 80's copyrighted contents were distributed in so-called Bulletin Board Systems (short: BBS). The dial-in into these forums was not as common as today and typically only technically interested people met there.

In these small communities, it was important that members actively supported the community before downloading, for example by uploading their own content or commercial software with removed copy protection. Commercial interests were almost not existent. At the end of the 1990s, the law enforcement took stronger action against this community.

This led to uncertainty among many participants, who now regarded the support of the scene as too great a personal risk. At the same time, the Internet, as we know it today, began to gain popularity. As a result, many warez from the BBS were uploaded and made accessible to everyone. These two factors were mainly responsible for the decline of the Bulletin Boards.

World Wide Web

Various, mostly commercially motivated ways of obtaining illegal copies of media have developed to this day on the Internet. Sites like Kinox.to or Bs.to provide hyperlinks to movies and series freely. According to an estimate of the Alexa.com website, these two were the 36th and the 23rd most visited websites respectively (Alexa, 2016). The small communities of the 1980s and 1990s, which in their time had made only little access to copies possible, have now been replaced by websites with millions of clicks. Everyone with an Internet connection can access them, and banners and similar advertisements monetize this massive access. According to the Motion Picture Association of America (MPAA), today's warez scene is pyramid-like structured (MPAA, 2006). The so-called suppliers procure the material, for example by filming cinema performances, and sell these recordings to replicators and release groups. They multiply the material explosively and make it available to other people, the facilitators. They download the content from the servers of the release groups, which are also called top sites, and upload it to publicly accessible sites. Once this has been done, the masses can access many different offers to access the illegal material. In this way, a few sources supply the entire Internet with warez. A more detailed view on the warez scene can be found in the article by D'ecary-H'etu et al. (D'ecary-H'etu, Morselli, & Leman-Langlois, 2012).

Peer-to-Peer Networks

A peer-to-peer (P2P) network describes a network architecture in which all network participants have equal rights. Unlike a client-server infrastructure in which clear roles are assigned, nodes in a P2P network can both provide and retrieve services. Most P2P networks use the infrastructure of the Internet as a basis and are organized centrally or decentrally depending on the implementation[25]. Since early P2P networks allowed a simple identification of peers, for example by their IP address or similar identifiers,

many approaches for monitoring have been documented. Some are more general (Banerjee, Faloutsos, & Bhuyan, 2007) and include legal discussions (Smith, 2003). Others aim at specific protocols. Chotia et al. address BitTorrent monitoring (T. Chothia, Cova, Novakovic, & Toro, 2012), Yang et al. (Yang, Ma, Song, Cui, & Zhou, 2006) discuss monitoring eMule, Saroiu et al. (Saroiu, Gummadi, & Gribble, 2003a) address Napster and Gnutella.

Private peer-to-peer networks extend P2P networks by various access restriction mechanisms like the allocation of passwords or keys. In a more special version of a private P2P network, the so-called Friend-to-Friend-Network (F2F), exactly these possibilities are used. With F2F networks, it is also not possible to register participants of the network outside their own friends list. These strategies obfuscate the activities within a file sharing network. An investigator cannot directly approach participants and scan for offered illegal files. He needs to get the trust of users and become a member of the network.

One of the best-known P2P networks still in use today is BitTorrent. The BitTorrent protocol is a decentralized structure for distributing data between users, the peers (Cohen, 2003). A central server, also called a tracker, keeps track of all peers who want to download a file. When a new peer connects to the tracker, it gets the addresses of some other peers who have already downloaded the file or are still downloading it. The peer will now begin to download the file, divided into small pieces, from several other peers. So the individual users, not dedicated servers, provide the bandwidth here. Since the different peers have a direct connection with each other, criminal prosecution of the different participants is possible without great effort (T. Chothia et al., 2012), if they do not protect themselves with VPNs or the like. It has also been shown that in some cases this prosecution is erratic (Piatek, Kohno, & Krishnamurthy, 2008).

The Usenet

The Usenet is a decentralized network where users exchange messages via "news servers". It consists of many servers that connect to each other and exchange messages. It can be seen as a direct successor of the already mentioned bulletin boards. To participate in the message exchange, users need a newsreader, which displays the postings from one of the Usenet servers. Through this newsreader, the user can also reply to messages and open new threads. The messages are then sent to the news server, which forwards them to all servers connected to it. Other users can retrieve this message even if they are connected to another news server. Messages are sorted in subhierarchies. Copies of software and other media are mainly exchanged in the alt.binaries subhierarchy (Anonym, n.d.), which is further subdivided for the different media types. Since these subhierarchies cause a lot of traffic, they are usually only offered by commercial news servers that require a monthly usage fee. The data exchange is encrypted and not logged, it is therefore very difficult to prosecute the individual users. However, there are ways to remove copyrighted material from the Usenet. A complete prevention of illegal data exchange is difficult due to the decentralized nature of the Usenet.

Private FTP servers

Small groups who want to exchange data usually do so via FTP servers. These privately operated servers are usually rented abroad with fake address data. Criminal prosecution is virtually impossible if the servers are configured correctly: access is only indirect, encrypted and not logged. This is coupled with the fact that only a few people even know about the existence of such a server.

Sharehoster

Sharehosters, also called one-click hosters or cyber-lockers, allow users to upload and download files on dedicated servers. Downloading files is only possible if the user knows the link to a file. This link usually consists of a pseudo-random sequence. These links are usually exchanged over external pages. As the servers operate in countries with less strict copyright laws, it is difficult to track individual downloaders due to limited legal support. Antoniadou et al. discuss this in more detail in (Antoniades, Markatos, & Dovrolis, 2009). The most popular case may be Megaupload, a sharehoster that paid for uploading content and became subject of a massive criminal investigation leading to its shutdown (Kang, 2012).

Obfuscation Strategies

Independent of the strategy actually used for obtaining warez, the IP address is visible to the downloading party at the point where the file exchange from one user to another occurs and may therefore potentially reveal the identity of the other peer:

the IP address is matched to the user by the respective Internet provider.

An obvious and effective method of obfuscating one's own identity is the use of public accesses without the need of authentication. The IP address in this case only leads to the public access, but not the actual user. However, it requires visiting a public access device and is usually subject to limited Internet speed.

The use of a Virtual Private Network (VPN) is logistically less demanding. The actual purpose of a VPN is the private communication with devices in a locally limited and shielded network, such as the intranet of a company, without being physically present there. A VPN opens a tunnel from the user to a service provider. When accessing the Internet via VPN, the user appears to come from the country of the VPN server and uses the IP address range of the provider.

The effect is similar to the use of a seedbox. Here, the user rents a virtual or physical machine from a third party on which he runs his file sharing client. Periodically, the user connects directly to the seedbox to download the accumulated files and issues new commands.

In both cases, the protection of the user's identity is the responsibility of the service provider, either the VPN provider or the host of the seedbox. The improvement of privacy depends on the service providers. China's "Great Firewall" is an example of censorship efforts that were initially bypassed by using VPNs and are increasingly accompanied by technical and political measures to suppress various evasion strategies.

PRIVACY-ENABLED FILE SHARING

Privacy mechanisms have been added to file sharing networks over the last 20 years. This section provides an overview of several approaches. They can be seen as an evolution of privacy away from early networks like Napster or Gnutella (Saroiu, Gummadi, & Gribble, 2003b) (Bellovin, 2001) or as a natural reaction to the file sharing monitoring (F.-S. T. Chothia, Chothia, & Chatzikokolakis, n.d.).

Beyond the technology we describe below, other file sharing networks have been developed claiming to provide user privacy. Among them are GNUnet, open source solutions RetroShare, OFFSystem and MUTE, as well as closed source Zultrax, Proxyshare, Nodezilla, Share and Winny. Most of them are of minor importance and are no longer in development.

Freenet

1

The freenet network (Clarke, Sandberg, Wiley, & Hong, 2001) basically treats all content as distributed files and allows the storage and exchange of large files. In combination with distributed storage, an overlay network, through which search queries and file transfers are routed, protects the identity of users. However, freenet's transfer rate is comparatively low, making it unattractive for exchanging large files. Freenet makes it possible to make the provision and acquisition of information anonymous by presenting itself as a decentralized data store that enables access to information anonymously with the help of encryption and clever routing. The freenet network must not be confused with Freenet.de, the access provider of the same name. The manner in which this is implemented in Freenet will be explained in the following.

Freenet consists of a number of equal computers (nodes) which are operated by individual users. Each node performs client and server tasks simultaneously. In addition, when installing the freenet software, each node releases storage space on its computer for use by freenet, in which both it and all other freenet nodes store, read, and forward content. The user defines the maximum size of this data store. Access to this encrypted data container is managed by the freenet clients. Once a file has been released, it cannot easily be removed from freenet access by the user. All these nodes and their associated data stores together form the freenet network. The content of each node's data store is encrypted. The user therefore does not know which data is currently on his disk or which information he is forwarding.

The transfer between the nodes also takes place in encrypted form, so the users cannot see which information is passing through the freenet via their computer. The freenet is therefore primarily a large, encrypted, anonymous file system with encrypted protocol information and not a file sharing protocol in the narrower sense. This is also a big difference in networks like Napster or Gnutella. With these networks, users make resources available that are located on their computers. These resources are available as long as the computer is connected to the network. Gnutella does allow a certain file to be redundant because it is stored by several users at the same time. After disconnecting all these users, however, the resource is no longer available.

In the freenet network, on the other hand, resources that are frequently requested are implicitly redundant in the network and move from node to node and are therefore available, regardless of whether the originator of the resource is connected to the network or not. Redundancy is therefore implicitly linked to the freenet protocol, regardless of user behavior.

This in turn means that freenet cannot guarantee that any specific information will be available forever. Because the number of computers involved limits the storage space, old information may be replaced by new information if the latter is frequently requested. However, it can be assumed that freenet's easy extensibility will always provide enough storage space for the information, as each new user also integrates new storage space into the network.

I2P

I2P (Astolfi, Kroese, & van Oorschot, 2015) is a software published under several free licenses, which allows the construction of an anonymous network. It has parallels to TOR and freenet. Similar to freenet, it is a decentralized darknet that stores routing information in a distributed manner. Routing, on the other hand, is an extended form of onion routing used by TOR and is called garlic routing. Similar to onion routing, the traffic is encrypted layer by layer. In addition, several requests are bundled into one packet and provided with an additional encryption layer (Schimmer, 2009). This also creates the analogy of

a garlic bulb. Another anonymization measure is the use of unidirectional tunnels, which means that requests and responses take different paths through the network. A tunnel corresponds to an encrypted connection in one direction between the sender of an inquiry and the processor, where other network nodes can also be crossed (Schimmer, 2009). This forwarding has the same effect as freenet, because it is no longer possible to trace whether a node has made or forwarded a request. The use of such unidirectional tunnels, however, increases the probability to pass an attacker's node within the network (Egger, Schlumberger, Kruegel, & Vigna, 2013). Addressing in I2P is based on Decentralized Hash Tables (DHT), so no directory servers are required as in the case of the TOR network. These tables contain information necessary to reach a specific endpoint within the I2P network. I2P offers the possibility to access the public Internet via an outproxy, but is not recommended because it is only about individual proxy servers. In addition, it provides web pages, so-called eapsites, and applications for sending anonymous mail, for example, but these are only internal to the network.

Tor

Tor is an acronym that stands for “The onion router”. It is an overlay network on the Internet that aims to protect the anonymity of its users (Syverson, Dingledine, & Mathewson, 2004). To achieve this goal all Internet traffic is encrypted using public and session key cryptography and sent through a network of several thousand relay nodes worldwide. Those relay nodes are hosted by volunteers who want to contribute to the network. To protect the anonymity of Tor users from attackers outside of the network all Internet traffic is encrypted and sent through the network on a predefined path using several relay nodes. This way an accessed website can only see the last IP address on the path through the Tor-network but not the originating IP address.

To protect against attackers inside the network the sent data is encrypted not only once but several times using public key cryptography. The name “The onion router” derives from this encryption because it is structured in several layers like an onion. Each of these layers of encryption can be decrypted by one of the nodes on the data's path through the network. If a node receives a data package, it decrypts the first layer of it to retrieve the data package with one less layer of encryption and an IP address to send it to. This way only the node where the data enters the network knows the originating IP address and only the node where it leaves the network knows the data's destination. Furthermore, if used correctly, none of the nodes knows the content of the data. In addition to anonymity enhancing options, Tor offers the possibility to host hidden services. Those are websites that can only be found within the Tor network. Due to the popularity of Tor these servers form a structure for which the term “darknet” is regularly used. Thereby they have become a synonym for the darknet.

Masking BitTorrent

BitTorrent (Pouwelse, Garbacki, Epema, & Sips, 2005) does not natively support measures to disguise user identity, but there is the possibility of private torrents. For these, a central tracker maintains a whitelist, and only passes information required for participation to trusted peers. Since BitTorrent also supports finding torrents using distributed hash tables, these private torrents depend on clients not overriding the appropriate flag in the torrent metadata.

BitTorrent via Tor: In this scenario, the user disguises his identity by using the Tor network as a proxy. Tor's network topology strictly differentiates between clients, nodes, and exit nodes, so the capacity of the network does not scale directly with the number of participants. Because file sharing requires a lot

of bandwidth (McCoy, Bauer, Grunwald, Kohno, & Sicker, 2008), Tor's network operators explicitly reject this application. Although the Tor network reduces performance, data exchange is faster than over freenet. However, the lack of official support increases the risk of misconfiguration and unwanted program behavior: For example, some BitTorrent clients transmit their own IP address assuming that the peers know it anyway.

BitTorrent via I2P: Unlike Tor, I2P supports both the UDP protocol and a number of ported BitTorrent clients, including the integrated I2PSnark client. Torrents that use the I2P network are isolated from torrents in Clearnet. Some clients can act as a bridge between the Clearnet and the I2P network by offering torrents in both environments. The owners of these bridges do not protect the privacy network.

OneSwarm

OneSwarm (Isdal, Piatek, Krishnamurthy, & Anderson, 2011) is a file sharing client that was initially released in 2009 and maintained until 2011. OneSwarm allows file sharing as a classic BitTorrent client, in a circle of confidants or through an independent overlay network that disguises the identities of the participants. This last operating mode promised significantly better performance than freenet and BitTorrent via Tor. It has been the subject of forensic investigations (Prusty, Levine, & Liberatore, 2011) aiming at identifying clients using it for sharing child porn.

The public part of a 1024-bit RSA key serves as a permanent pseudonym. Familiars can be added manually, using external means of communication such as email, or as a centrally managed group. In addition, public servers mediate peers not trustworthy (all peers who have not been explicitly trusted are not considered trustworthy). In the network, messages to these peers are randomly delayed or dropped altogether to prevent conclusions about neighboring nodes.

Since the network can only receive data that was previously sent, it is necessary to encourage peers to participate in the network. To this end, the amount of data received and sent by each immediate peer is compared. If a peer receives significantly more data than it sends, its priority drops during peak periods. Peers with extreme discrepancies are completely excluded.

RELATED WORK

Already in 2002, Biddle et al. mention the lack of anonymity in then popular file sharing networks and point to solutions like freenet (Biddle, England, Peinado, & Willman, 2003). They call any content distribution network darknet, which satisfies a number of requirements, but anonymity or privacy are not among them.

In 2003, the numerous lawsuits regarding warez traded on the Internet via various channels were summarized and discussed by Goldman in (Goldman, 2003). It provides a good overview on the viewpoint of criminal actions connected to warez.

In 2010, Chaabane et al. (Chaabane, Manils, & Kaafar, 2010) found that roughly 25% of Tor traffic was used for BitTorrent file sharing. They were also able to attribute individual file names shared and showed that new video games, movies and series to be the most frequently shared content over the combination of BitTorrent and Tor. The work by Zhang et al (Zhang, Dhungel, Wu, Liu, & Ross, 2010) on private BitTorrent sites from 2010 found that there were roughly twice as much public torrent sites as there were private ones.

Le Blond et al. (Blond et al., 2011) in 2011 discuss attacks able to trace BitTorrent streams on Tor by controlling a Tor exit node and monitoring outgoing traffic. This is possible as 70% of the users only connect to the BitTorrent trackers via Tor and share content unprotected. They provide various insights on the usage of file sharing via Tor. In their samples, the most popular content was shown to be pornography.

A more detailed analysis for content shared via I2P (masking both Gnutella and BitTorrent) and freenet is provided by Aked (Aked, 2011) in 2011. Child pornography was claimed to make up more than 50% of the content shared via freenet in this investigation. In I2P, the presence of child pornography was minimal. Movies, pornography and TV shows were the most prominent content here.

In 2013, Li et al. (Li, Erdin, Gunes, Bebis, & Shipley, 2013) published an overview of anonymity technology usage where also Tor and I2P are mentioned. They identified 61,798 Tor relays and 2,267 I2P relays. But they also found out in an experiment, that only very few peer-to-peer users utilized privacy protection: of sampled 128,422 IP addresses of peer-to-peer users, only 58 used a privacy mechanism like Tor.

A study from 2014 (Biryukov, Pustogarov, Thill, & Weinmann, 2014) analyzes 3050 hidden services with respect to their content. Here only 7% addressed software downloads.

In 2016, the European Union Intellectual Property Office (EUIPO) published a report (Deloitte, 2016) executed by Deloitte Spain, in which it was found that more and more file sharing sites were moving into the darknet, especially the Tor network. Privacy protection of file sharing users is stated to be successful in this report, as monitoring and take down notices known from the Cleartnet are not working in the Tor network. In combination with cryptocurrencies like Bitcoin, Tor is identified as a significant challenge for anti-piracy efforts.

In the same year a report by Inteliagg (Inteliagg, 2016) concluded that 29% of analyzed Tor hidden services addressed file-sharing information, significantly more than drugs (4%), for example.

A report published in 2018 by irdeto (irdeto, 2018) shows the still high numbers of P2P file sharing. In 2017 6B downloads of TV shows and 4.6B downloads of movies were monitored in the BitTorrent network. Privacy mechanisms are not mentioned in this report.

CONCLUSION

File sharing networks for the illegal distribution of copyrighted material and the darknet were synonyms in the 2000s. Since then, the term darknet has become more connected to privacy networks like Tor. However, the development of monitoring technology to fight online piracy has also changed the file sharing networks. While many users still use file sharing without privacy protection, the amount of file sharing among networks like Tor and I2P has become significant. For Tor, the use of file sharing has even been discouraged officially due to the vast amount of traffic it causes.

Content shared via file sharing darknets seems to be similar to other file sharing networks and consists of movies, TV shows, music, pornography and software. In freenet, the amount of child pornography is said to be alarmingly high. This is a good indicator of the risks of privacy networks: anonymity and the lack of censorship provide tools also attractive for criminal activities far beyond copyright violations.

ACKNOWLEDGMENT

This work was funded by the BMBF project "PANDA". It was made possible by the contributions of our students Karola Marky, Annika Schaefer, Paul Mohr and Philipp Norbert Skrinjar.

KEY TERMS AND DEFINITIONS

Darknet: From the perspective of copyright violations, any network used for the illegal distribution of files can be called a darknet. From a privacy perspective, a darknet is a network providing anonymity for its participants.

File-Sharing: Offering and transferring digital files via various channels of the internet, usually in a decentralized manner.

IP Address: Internet protocol address, usually the basic identifier of a computer participating in the internet. It can be seen as a pseudonym of the user of the computer and can be connected to the identity of the user by his internet service provider.

Peer-to-Peer Network: A network of nodes with usually equal rights and responsibilities. The nodes are usually computers of Internet users where a software with the peer-to-peer protocol is running.

Tor: Short for The Onion Router. A privacy network based on onion routing and encryption.

Warez: Term for illegal digital goods, usually software or multimedia files.

Academic Integrity of Global Digital Masked Bandits Lurking the Deep and Dark Web

INTRODUCTION

Educators in the K-20 system are faced with an important issue as it pertains to academic writing and research. There are many studies on academic dishonesty and cheating at all levels of education. Administrators and faculty in education need to be aware of the entrepreneurial gravity of this scheme and be proactive in communication by informing all stakeholders to develop policies to this academic epidemic. This article will also research the motives of academic dishonesty, deep web schemes to defraud, avoidance of criminal prosecution, and non-conventional intellectual warfare while making recommendations for internal change and reform. The purpose of this article is to enlighten practitioners and researchers to include students and educational administrators about the growing concern of plagiarism, unintentional plagiarism, defrauding funding sources, governmental agencies, educational institutions, perspective employers, and affixing serious long-term consequences and liability to participants and placing a negative stigma on brand reputation and further stress on academia.

BACKGROUND

There is a chasm between policy and research, and there is a need to increase the policy impact of educational research (Gillies, 2014). Gillies (2014) claimed knowledge activism is one method that research can influence policymaking. Fowler (2013) commented that in the event of a public problem, policymakers must have a policy process to examine any policy issue that is under debate. Public policy should be grounded by research, especially research on the phenomenon of academic integrity in a

DOI: 10.4018/978-1-5225-9715-5.ch012

technologically driven society, especially with access to the deep web. When faculty at institutions of higher education recognize students' academic dishonesty tactics, they must *take corrective action* by following the university's policies by guarding the integrity of the course curricula (Larkin, Szabo, & Mintu-Wimsatt, 2017). Löfström, Trotman, Furnari, and Shephard (2015) compared academic integrity to a skill. Academic dishonesty is a phenomenon witnessed in higher education where the decision to cheat is a deliberate choice for students (Seals, Hammons, & Mamiseishvili, 2014). Moten, Fitterer, Brazier, Leonard, and Brown (2013) explicated that due to the lack of face-to-face interaction between students and faculty and because of online learning, students have a stronger opportunity to engage in cheating, which is described as defrauding the intellectual property of the institution, plagiarizing, and violating university/college policies.

No part of the educational system is immune from dishonest and illicit non-traditional schemes to attack its integrity. Although this behavior is prevalent in higher education, it is also a disturbing phenomenon witnessed at all educational levels in society. McCabe, Treviño, and Butterfield (2001) made mention of a study that by the time high school students enter college, they have had previous years of practice regarding academic dishonesty. In addition, if college freshman continues to cheat their next few years while in college, they consider high school to align with college practices of academic dishonesty. McCabe et al. conducted a ten-year research study of college students regarding cheating that occurs in academic institutions to include the importance of having integrity/honor code policies in place. Research indicates that due to the personal and professional challenges students face today, they tend to practice dishonest study habits, therefore the reason for the implementation of policies and honor codes (McCabe, Treviño, & Butterfield, 2001). McCabe et al. explained that

No campus can assume that its students, incoming or returning, will take the time to familiarize themselves with campus rules about academic integrity on their own. Even if they did, an institution's failure to emphasize for its students the high value it places on academic integrity sends the message that it is not a high priority. (p. 231)

Understanding the reasons, although not condonable, for cheating is an important component in policy decisions (Marsh, 2011). Preserving academic integrity is a topic for all stakeholders that have been challenged by the onset of new technology and changed viewpoints of the millennial generation (Dyer, 2010; Moten, Fitterer, Brazier, Leonard, & Brown, 2013; Trenholm, 2007). The increase of technology usage has increased violations of academic integrity: an increased connectivity, collaboration, and social networking (Dyer, 2010; Jiang, Emmerton, & McKauge, 2013; Marsh, 2011). Online courses mean reduced supervision and greater availability for collaboration. Another challenge for educators includes teaching students correct ways to use and cite online sources. A digital divide exists between instructors and students. *Millennials* are adept at using computers, smartphones, and new technologies to gain answers for assignments, exams, or papers (Dyer, 2010).

A notable study undertaken by the Josephson Institute on Ethics of nearly 30,000 public and private high school students in the Los Angeles California area found 30% admitted to stealing from retail stores and 25% admitted to stealing from friends and family members (Zicari, 2008). Zicari (2008) noted another 64% admitted to cheating in school examinations, and 38% admitted to cheating multiple times in their school assignments. Thirty-six percent of students admitted to stealing digitized academic work by plagiarism tactics from the Internet. The students who participated in the study stated 93% believed their behavior was ethical. Seventy-seven percent of the student participants stated they are far more ethical than their peers. This is an epidemic in today's educational system to include the entire world.

The deranged Unabomber, Theodore Kaczynski, wrote in his manifesto how the world would be far more dangerous and destructive with conflicts among people, processes, and digital technology. Social acceptance of apathy and corrupt practices does not provide for a healthy society of critical thinkers with the skills to advance communities, people, and nations. This technology is causing our usurping of critical thinking by taking the easy way out, which is one reason why students cheat. Diamond (2017) quoted Andrew Sodroski, a television executive producer, regarding Kaczynski's manifesto as, "What the manifesto has to say about our relationship with technology and with society is truer right now than it was when Ted published it" (para. 5). After all these years, Kaczynski was correct, as the Internet has brought people closer to information, but also false information and illegal means to obtain information. Students and other researchers have become dependent upon the technology and have lost reason by allowing technology to take over their critical thinking to merely plagiarizing and searching for ghostwriters than researching and writing their papers, articles, and other published work.

Once a service, such as technology, has been made available, people could decide, why not use it, is at all that bad or illegal? Like any crime, people feel that if it is wrong and no one is stopping them; why not continue to use the information online? In addition, people feel that if it is online, it must be true. Kaczynski (1995) wrote about how people can be dependent on the technology as well as the mass-communication media.

In many cases the new technology changes society in such a way that people eventually find themselves forced to use it. . . . Another reason why technology is such a powerful social force is that, within the context of a given society, technological progress marches in only one direction; it can never be reversed. Once a technical innovation has been introduced, people usually become dependent on it, unless it is replaced by some still more advanced innovation. (p. 16)

Creative cheating schemes have become commonplace. The quick and easy approach to academic studies has eroded the quality, rigor, and derailed students' critical thinking skills of students throughout the world. Subscribers and payees of paper mills and the compliment of ghostwriters all collectively provide *Material Support* to international crime cartels, a federal felony 18 USC 2339A. It is reasonable to have conversations that global digital sycophants who have used clever schemes to defraud, cheat, have attacked authentic leadership and game our critical American infrastructures with agendas that we argue are misaligned to our cultural norms, our educational system, and our Democratic foundation. Additionally, the construct of academic integrity and consequences of academic dishonesty is a challenge that academic institutions face as the international population increases at American universities and colleges (Gillespie, 2012).

FOCUS OF THE ARTICLE

Blum (2009) admonished there must be communication about plagiarism between students and faculty, and international students must be cognizant of institutional policy on academic integrity. Cohen (2007) illustrated that variances in cultural could be misinterpreted with negative consequences for international students. Furthermore, it was discovered that ideas of cheating and students' shared work, which is acceptable in numerous cultures. Surprisingly, this is viewed as an honorable act in having the ability to aid others in this manner, as sharing of information does not constitute any behaviors of honesty, character, and integrity (Cohen, 2007). Students do not consider that academic dishonesty is unethical,

and in some cultures, it is considered inclined, a challenge and/or acceptable behavior if noticed by their faculty. Numerous cases have demonstrated that students were insulted by allegations of wrongdoing, and due to their moral beliefs, believe it would be seen as a lack of character by not assisting their peers. Cohen discussed an event that pertained to a student from Asia who took great joy in the ability to cheat; however, without hesitation would admit to the student's unethical behavior if caught. Another situation deemed acceptable is the forgery of documents to leave native countries. If for the greater good, it is not perceived to be an act of dishonesty. Integrity in higher education is a culturally derived term and has various meanings to individuals from a myriad of cultures. International students contribute to American institutions of higher education; therefore, the policymakers within higher education are responsible for minimizing academic integrity cultural barriers (Smithee, 2009).

Academic misconduct. Weber-Wulff (2014) identified various forms of academic misconduct: (a) contract cheating, (b) falsifying data, (c) ghostwriting, (d) honorary authorship, (e) paper mills, (f) plagiarism, and (g) unknown ghostwriters. Academic cheating, as noted by several researchers, have concluded that within schools and universities of many countries, forms of dishonesty is not a novel occurrence. It has been observed that students like to utilize a plethora of methods to obtain what one would consider undeserved privileges that comprise of masking the truth in their research (Bachore, 2016; Iberahima, Husseinb, Samatc, Noordind, & Daude, 2013; Sarita, 2015).

Contract Cheating

Contract cheating is the process of bidding between independent contractors for assignments that have been uploaded to a website. The client selects an author based on the lowest bidding price, and services are paid through PayPal (Weber-Wulff, 2014).

Walker and Townly (2012) found there is an increase in contract cheating, and Wallace and Newton (2014) investigated postings from the freelancer and TransTutors website to postulate whether a shorter time frame for the completion of assignments would decrease the incidences of contract cheating. Contract cheating evades plagiarism detection software since the submitted work is original work.

Falsifying Data

Falsifying data is the manipulation of data to meet personal agendas in biased research. In a qualitative study, researchers have to write sections on ethical considerations, trustworthiness, and potential research bias. The ethical considerations are based on how the researcher maintains the ethics of the study and preserves anonymity and confidentiality while keeping documents and digital recordings secure. Trustworthiness demonstrates that the study is valid and reliable. Inaccuracy and a lack of corroborating evidence affect research leading to misinterpretation of research and falsification of data. The researcher must account for potential bias and remain subjective and neutral to various viewpoints (Creswell, 2013).

Ghostwriting

Ghostwriting is the process where an author does not receive acknowledgment for writing assignments. Companies hire ghostwriters to write custom-written papers. Because the company acts as an intermediary, the ghostwriter remains anonymous. There is no contact between the client and the ghostwriter (Weber-Wulff, 2014).

Paper Mills

A paper mill maintains papers collected with an author's permission in a large database. The customer purchases access to this database under the pretense of learning to structure the paper. The paper mill cautions the client to use the paper only as a resource. As cited in Wallace and Newton (2014), Turnitin found 7% of higher education students have reported purchasing a paper during their undergraduate studies.

Plagiarism

Based on literature discovered, researchers have classified many types of plagiarism: (a) copy and paste, (b) translations, (c) disguised plagiarism, (d) shake and paste collections, (e) clause quilts, (f) structural plagiarism, (g) pawn sacrifice, (h) cut and slide, (i) self-plagiarism, and (f) other dimensions like collusion. There has been a hike in plagiarism over the past decade due to the access to technology. Plagiarism is described as including other researchers' thoughts, verbiage, data and/or findings (Bachore, 2016; Sarita, 2015; Weber-Wulff, 2014).

Unknown Ghostwriters

Weber-Wulff (2014) described an "unwitting ghostwriter" to be a thesis writer with archived work on a compact disk with a digital version at the university library. Students access these digital versions to modify, use, and claim ownership to the thesis. Technology has revolutionized higher education and has provided a vast amount of information accessible to students. The significant number of companies advertising editing services indicate a widespread problem of academic misconduct (Weber-Wulff, 2014). However, are students seeking editors for format only, or rather editors to create and/or rewrite existing papers? Institutions use plagiarism detection software to compare essays against a database of work, but many paper mill companies guarantee original work by a ghostwriter and screen the work for plagiarism before distributing it to clients. The cost ranges from \$20.00 to \$40.00 depending on the subject and turnaround time needed. Software like Turnitin is used to find counterfeit papers but does not intercept custom papers. Wallace and Newton (2014) believed contract cheating to be a problem; although this phenomenon is widespread, there are few studies and few approaches addressing it. Theoretically, contract cheating is original work that avoids detection from originality detection software. This makes it difficult to estimate the extent of contract cheating. Wallace and Newton suggested a reduction in turnaround time for due dates of assignments may give students less time to contract an independent contracted writer, but would not eliminate the occurrence of contract cheating. Most likely, the student will have a due date, but if a ghostwriter does not fulfill his or her obligation to the student, the ghostwriter is also committing fraud by receiving funds and not adhering to the contract for the student.

Fraud

Academic dishonesty is a concern for institutions of higher education as the increase in technology provides a path to new ways of committing academic fraud and electronic dishonesty (Wallace & Newton, 2014). Stanford University issued an alert of a high number of students suspected of cheating. Even though students accept the terms of the honor code, students are risking the consequences of cheating (e.g., failing grade, suspension, expulsion). In 2013, 83 students violated the honor code; a first violation results in a suspension of one term and 40 hours of community service (Mercury News, 2015).

The conduct of cheating violates both federal and state felony statutes-law(s), and a person(s) or institution can be criminally charged-convicted individually or in a conspiracy case. Double jeopardy does not imply if charged or convicted in both the federal and state courts based on the same conduct in the defense argument, but for the purpose of this paper, the focus will only be based upon the federal law (i.e., U.S. Criminal Code). Aside from the criminal liability outlined, there are real concerns for civil suits, which can also be applied simultaneously for the same conduct as the criminal charges. The Federal False Claims Act is a tool that can reign in unethical conduct and encourages the reporting of unethical conduct and violations of federal law. Many states have adopted the provisions of the Federal False Claims Act; any person or institution can be dually charged with violations of federal-state False Claims Act offenses arising from the same conduct.

By applying the law to cheating scandals, it sends a clear message to stakeholders to discourage individuals from cheating. Trying to assert a defense of ignorance fails to provide legal protection if the person or institution knows or suspects fraud or organized schemes to cheat or defraud. For example, any person or institution having personal knowledge of any conduct that is outlined in this paper and other activities defined by statute as illegal conduct can lead to the felony prosecution of persons and or institutions that fail (Misprision of a felony) to report any conduct which is illegal (18 USC § 4).

Under the federal criminal code, it is important to underscore the law of conspiracy (18 USC § 371 & 1349). In summary, this provision of the law includes any (overt acts) or attempt(s) to do an act in violation of a crime; the crime is punishable under the same provisions as if the act had been completed. Under the theory of a conspiracy, any person-business in the conspiracy is liable for the acts of others whether they know the others involved and the statements of others are attributable to others. The 18 USC 1346 is a federal criminal statute that covers Honest Services for any conduct that leads to an artifice or scheme to defraud.

Any proceeds or property acquired by means of academic cheating are subject to either federal or state administrative-criminal asset forfeiture proceeding. Thus, there is an added disincentive for engaging in the conduct presented in this paper (18 USC § 1956). It is nearly impossible to effectively escape criminal-asset forfeiture liability in these examples. The suggestion is to remain proactive and develop affirmative programs and policies aimed at preventing and eradicating serious forms of educational cheating.

At the University of California, San Diego, 600 students cheated in 2014 by copying tests, using notes, helping others, or purchasing papers online. As a response, the university implemented an Academic Integrity Office to handle student cheaters (Regents of the University of California, 2015). Students who earn grades through academic dishonesty undermine values of the institution; serious consequences include the destruction of academic records and reputation and an inability to matriculate (Dyer, 2010).

CNN reported cheating on papers is a “booming Web business” and reported 90% of the requests for online academic papers to come from the United States. DomainTools purported essaywriters.net solicits writers to write these papers research papers, book reports, and coursework on syllabi. Various paper mill enterprises make claims they offer original writing services provided to customers as a reference only and are not to be used without proper citations. This assertion is deceptive and does not offer any statement reporting the true identity of the ghostwriters who authored the work. Clearly, there are few real customers other than students who purchase academic papers to defraud professors, academic institutions, financial loan service providers, and administrative-regulatory oversight agencies. It is not possible to sell the volume (based upon customer testimonials who admit to using the paper mill services to order, purchase, and submit papers to schools and colleges to pass courses) of scholarly papers for non-academic use.

There is a myriad of clever schemes designed by paper mill enterprises that actively solicit customers and students. These digital masked bandits conspire and consequently defraud academic institutions/loan servicing providers, and federal-state administrative and regulatory oversight agencies by using these fraudulent schemes with the intent to misrepresent.

An example of a simple scheme includes federal felony crimes of mail or wire fraud communications technology and other means to communicate the scheme including regular or express mail services. In summary, paper mills must operate using means to communicate. Under the federal mail and wire act, any person-business or other entity involved in a scheme to defraud (attempts are included) using the mail or wire systems are crimes (18 USC § 1341 and 1343).

A federal fraud conviction is most likely to include mandatory prison time, fines, or probation. If sentenced to prison, the sentence could range from 6 months to 30 years for each act. Home confinement is an alternative sentence that is rarely applied. The offender is now labeled a convicted felon restricting the rest of his or her life. Fines are another punishment for a violation of fraud and could be as much as a \$250,000 fine for each violation. Finally, restitution and probation are additional sentences imposed with a guilty conviction of fraud (Theoharis, 2015).

The volume of activity and sales of papers is unquantified but remains staggering if one were to believe the published testimonials on the websites of paper mills and YouTube posts endorsed by student customers. It is likely the paper mill services under report and or fail to report earnings to federal and state taxing authorities which also become crimes (26 USC § 7201).

A national investigative-enforcement strategy could prevent-control this problem. Adding enhanced crimes, such as false statements or causing/keeping false records: (a) student grades and educational reports (18 USC § 1001), (b) theft (18 USC § 666), (c) the Racketeer Influenced and Corrupt Organizations (RICO) Act (18 USC § 1961-1968) and (d) financial institution fraud crimes (18 USC § 1344), Honest Services Fraud 18 USC 1346 and 1349 (Attempts) can be applied as countermeasures and investigative tools. Each carries additional criminal sentences and asset forfeiture penalties (18 USC § 1956).

Motives for Academic Dishonesty

It is essential to bring up cheating as early as possible, as it will aid in guaranteeing ethical behavior in practice since academic dishonesty is linked with unethical business practices (DiVall & Schlesselman, 2016; Iberahim, Hussein, Samat, Noordin, & Daud, 2013). As educators, it is difficult to comprehend why students continue to cheat and or plagiarize, however, as educators, we have also forgotten the extreme pressures that students experience. Now, this in no way, shape or form means that educators must water down the curriculum to prevent cheating, but it gives insight as to one of the possible reasons why it occurs. More specifically, DiVall and Schlessman (2016) indicated that pressure, from students, is heightened by the students' peers or even families. It was further illustrated that having such pressure can cause students to be greatly grade-oriented, instead of being outcome-oriented.

According to research, the students desire to get ahead is one of many reasons to engage in academic misconduct. Other reasons for plagiarizing and cheating are due to, being scared of failing, having bad time management skills, and the longing to help a school colleague (DiVall & Schlessman, 2016). Naghdipour and Emeagwali (2013) further indicated alternate reasons for academic misconduct, which comprise of both psychological and individual factors such as, "gender, low GPA, age, narcissism, competitive achievement and contextual factors such as the existence of honor codes, disciplinary rules and learning environment" (p. 261). Iberahim et al. (2013) explicated that research illustrated an abundance

of reasons that students engage in academic misconduct: (a) grades, (b) big classes, (c) struggle for jobs, (d) cheating culture that is common within the community, (e) sincere deficiency of comprehending of what is plagiarism, (f) personal values, (g) no respect for authority, (h) opportunity, and (i) cheating having a nominal effect on others.

Results for a study conducted by Iberahim et al. (2013) revealed that a majority of students took part in academic dishonesty, as the faculty member was okay with that form of behavior. DiVall and Schlessman (2016) stated that faculty members could lower the percentage of students cheating by fabricating seating charts or issuing various versions of tests on test day. However, faculty members have indicated that taking these measures have proved to be time-consuming, and therefore, did not implement these procedures. Moreover, as technology continues to progress, it has deemed to assist students in cheating more and make it further challenging for professors to prevent this misconduct (DiVall & Schlessman, 2016; Naghdipour & Emeagwali, 2013). University administrators need to make strict policies and procedures as well as streamline the process to hold students, faculty, and other stakeholders accountable.

Academic integrity threatens ethical leadership and citizenship and permeates all aspects of life (a) validity of assessments, (b) equity in grading, (c) diminishes the reputation of institutions of higher education, (d) workplace behavior, and (e) societal context. Academic dishonesty has social consequences reaching far beyond the classroom (Dix, Emery, & Le, 2014). There is a relationship between human values and ethical leadership. Moral education is the center of virtue ethics (Marsh, 2011). Marsh (2011) conducted a mixed-mode analysis to find circumstances to justify cheating. Marsh surveyed 401 undergraduate students at a Carnegie I research university, 66% were freshman (59% were female, 41% male), and 7% spoke English as a second language. One hundred and forty-four students claimed there are circumstances that justify cheating. There were six reasons that justified cheating: (a) denial of responsibility, (b) denial of injury, (c) condemning the condemners, (d) self-fulfillment, (e) appeal to higher loyalties, and (f) denial of the victim. There were subcategories (a) accidents, (b) crisis, (c) scapegoating, and (d) accidental plagiarism. Additional reasons included material or tests that were too difficult or lack of explanation of the material. Students reported paraphrasing might be considered plagiarism.

Other driving forces for academic misconduct include individual pressures, time constraints, and availability of online sources (Jiang, Emmerton, & McKaige, 2013). Blum (2009) contended competency-based education, increased the cost of college tuition, and the value of earning power contribute to the culture of academic dishonesty in higher education. Shifting generational attitudes and information technology are two factors that perpetuate the lack of academic integrity (Dyer, 2010; Manly, Leonard, & Riemenschneider, 2014). In fact, Manly, Leonard, and Riemenschneider (2014) claimed an instructor-student disparity existed over the perception of cheating. Instructors held a different viewpoint of cheating behaviors than students. In most cases, students did not consider behaviors associated with information technology to be cheating, and the top three behaviors using information technology included (a) electronic devices during exams, (b) using ideas from an online purchased paper, and (c) cutting and pasting data from the Internet. Dyer (2010) maintained millennials had worked collaboratively using the Internet since elementary school, and students are not aware that copying and pasting from online resources is a violation of academic integrity. The concept of integrity has evolved, and there is a marked difference in the perception of acceptable academic behavior.

For 10 years, no one knew Dave Tomar, a once ghostwriter who wrote over 3,500 papers, who stated that he engaged in ghostwriting for a living to aid him financially. He started writing papers for students, on all subjects, out of college and worked for other online companies. He initially made 10 to 20 dollars a page and was then paid up to 40 dollars to help students cheat, as he described them as being too lazy

or incompetent. Tomar revealed that in regards to those who are guilty of cheating, it is not an ethical question that one would ask, but rather it is a practical question. Tomar learned of two suspicions while ghostwriting, of which one was that numerous students are given and accept the message that they are going to school to obtain grades as well as a degree. His second suspicion was the number of students who are going to school without adequate preparation and how students are deficient in critical skills.

As early as 2003, the Secretary-General for Interpol Ronald Noble testified before the House Committee on International Relations in the United States Senate and stated the link between the trafficking of Intellectual Property Crime Piracy, or theft of trade patents and business competitiveness-sabotage has direct ties to funding global Terrorist groups including Al Qaeda, Hezbollah, and Hamas. Various other experts cited in the review, have noted the vast wealth attributed to these crimes requires the use of capitalistic systems to be successful. Digital masked bandits can lurk in the dark web stealing trillions of dollars and remain relatively anonymous and hard to detect by traditional investigative means (Williams, 2008).

Ghostwriting Process

A student has a limited time to complete a paper, and a quick online search of *paper mills plagiarism mills* or *essay mills* produces several results. Although many of these companies claim to help the professional, the services are geared toward a specific client: the student. The websites offering academic papers boast an endless amount of testimonials; this information can be used against the company's interest and can be used as evidence in fraud cases. There are YouTube tutorials students have explained how to use paper mills. To illustrate the popular stance on academic dishonesty, one student explained successful strategies for cheating on an exam; this post received 20,947 likes and 6,560 dislikes (Ferasweelz, 2012). This evidence can be used in both state and federal cases and could establish a RICO investigation by the federal system; additionally, laws vary within each state (VOA Special English, 2014).

According to admitted scholarship ghostwriter Tomar (2012), this problem is rampant. As an illustration, a student receives an assignment with the professor's criteria, expectations, rubric, scoring guide, and format rules. The potential client searches for a paper mill company and selects one based on various factors. The paper mills have ghostwriters who could be scholars such as professors, graduate students, and/or freelance writers. Papers are written for all academic levels and disciplines and are not triggered by Turnitin or any other program that will detect plagiarism. The client includes payment information and then posts the topic on the paper mill board, which is comparable to a bulletin board format. A ghostwriter contacts the client directly to discuss the specifics of the paper based on the guidelines. The client's credit card is charged, and then the contracted writer begins working on the paper. By entering into an agreement, both parties agree to accept the resulting obligations and consequences. The ghostwriter then sends a final copy via email. The client can review the document and discuss possible changes or edits. If there are changes that will be made, there will be further discussion about pricing. The student only has to write his or her name on the title page of the paper and submit it to the professor, usually by email. This paper will not trigger Turnitin as plagiarized work, so then the professor grades it. At this point, the student has now stolen a grade, which is something of value.

Consider the hundreds of thousands of grades that are stolen and reported to various oversight agencies causing them to keep and transmit fraudulent data and to fund the student's education in this scheme to defraud. This conduct can be defined as theft and fraud because something of value (e.g., academic grade) was stolen. The testimonials posted on paper mill websites and YouTube indicates that income

could exceed hundreds of billions of dollars in revenue from these services. Tomar (2012) reported the conduct is unregulated and out of control. These examples underscore what is defined in the above sections as additional-potential crimes which include (a) false statements, (b) wire fraud, (c) mail fraud, (d) conspiracy, (e) RICO, (f) money laundering, and (g) financial institution fraud (e.g., banks, PELL, VA, financial aid), and (h) theft.

Consequences. Now that the student is involved in the overall scheme or a conspiracy, everyone involved in the paper mill companies (e.g., owners, ghostwriters, institutions, students) committed numerous violations of law and may be involved in an ongoing conspiracy. The vendor, end user, employers, governmental and private sector funding, and regulatory authorities and sources along with K-20 administrators and the faculty involved are all co-conspirators in a clever criminal scheme to defraud a myriad of entities.

Phony grades from students using fraudulent scholarly work from paper mills are ultimately reported, maintained, and transmitted to federal and state departments of education (and related administrative and regulatory agencies). This represents false record-keeping, and there exists no accrediting agency that has the means to track this information (18 USC § 1001).

As a result of this illegal conduct by paper mills, considerable amounts of revenue may be produced and laundered. The assets/monies are subject to asset seizure and forfeiture; this is an added incentive for law enforcement to initiate a criminal investigation into these organized schemes to defraud (18 USC § 1001).

Investigation

Academic fraud needs to be approached much like any other fraud case. In order to curtail academic dishonesty, proactive initiatives are generally productive options. Investigators should develop cooperating witnesses-sources, collect testimonials and other promotional evidence found on paper mill websites and YouTube. Investigators should follow the flow of money through electronic wire intercepts, tax returns, credit cards, and bank accounts, as well as subpoena records and financial-records search warrants. In the investigation, the Internet service provider (ISP) will provide a narrative content with the final goal of tracking the crimes all conspirators: students, witnesses, ghostwriters, and companies.

Additional Players

If an institution or individual has knowledge of a crime (schemes to defraud) and fails to report it, it is a violation of the US Code 18 Section 4 (Misprision of a felony), which is a federal felony violation of a law. In the recent cases of systemic academic corruption, the Atlanta Public School administration and faculty engaged in an ongoing scheme to defraud various organizations and its chieftains-participants landed lengthy prison sentences.

SOLUTIONS AND RECOMMENDATIONS

Weber-Wulff (2014) admonished the question of intent: (a) unintentional, (b) honest mistake, (c) poor referencing, or (d) purposeful deception may be difficult to discern, but university and college policy-makers need to address the problem of academic misconduct. Strategies to reduce plagiarism will affect learning, cheating, campus culture, and institutional image (Dix, Emery, & Le, 2014). Using online

detection services, providing plagiarism workshops, and educating students and faculty of the consequences of academic dishonesty may decrease the number of occurrences. Plagiarism policies need to be developed by training students and faculty, establishing a transparent policy, and testing random dissertations, theses, and papers (Weber-Wulff, 2014). By turning in early versions of term papers, research papers, and essays, students will be encouraged to complete original work.

Professors, teachers, and other personnel who detect plagiarism-unintentional plagiarism while grading papers need to have teachable moments for students who may not be aware of this type of behavior. Policy makers in universities and colleges, including the K-12 system, should have a policy in place that not only detects possible plagiarism but how to collect the documentation to support the detection. In addition, this policy should illustrate the process to determine whether a student was in violation of the plagiarism-unintentional plagiarism directives and if so create a paper trail and flowchart as described in Figure 1.

Löfström et al. (2014) explored the definition of academic integrity, how it should be taught, and whose responsibility it is. All surveyed groups agreed on several components of academic integrity including but not limited to (a) the importance of the research process, (b) knowledge of faculty to teach academic integrity, (c) academic integrity is more than following rules, and (d) ignoring minor inci-

Figure 1. Protocol for handling plagiarism

dences will not protect the university's reputation. It is essential to know the rules, teach the rules, and follow departmental and institutional processes. The use of honor codes could also be part of the solution (Manly, Leonard, & Riemenschneider, 2014). Gillespie (2012) ascertained academic advisors play a primary role by informing new students about plagiarism, explaining its consequences, and referring new students to campus resources. These academic advisors and faculty should also inform students of *unintentional plagiarism*. Unintentional plagiarism is when students and researchers poorly paraphrase by changing minimal words, changing intended meaning, or using words not part of his or her vocabulary. Additionally, quoting or citing poorly also is considered unintentional plagiarism. Academic integrity can be maintained by (a) educating students, (b) incorporating new technologies and styles of teaching like smartphones and online authorized study groups, and (c) policing students and enforcing policies (Dyer, 2010). Since culture plays a role, advisors should explore the perceptions of academic integrity, faculty from other countries, and other international students (Smithee, 2009).

CONCLUSION

The public policy of plagiarism, editing services, contract cheating, and use of ghostwriting need to be implemented. These policies and issues apply to the university and its business principles. As noted in Table 1, not all universities/colleges have a policy on unintentional plagiarism, nor did they have policies on fraud. This is a phenomenon that must be addressed internally as well as with accrediting agencies. The Center for Academic Integrity (1999) developed seven recommendations for every institution of higher education:

1. Have clear statements, policies, and procedures that are implemented.
2. Inform and educate the community about academic integrity.
3. Practice these procedures from the top down. Follow and uphold them.
4. Have an equitable system to adjudicate violations.
5. Develop programs to promote integrity.
6. Watch trends in technology that affects campus integrity.
7. Assess the efficacy of policies and improve upon existing ones.

Policy needs to be formulated and followed by engagement and commitment. Such initiatives will reduce fraudulent acts. This is so prolific; transnational organized crime syndicates will exploit opportunities to cheat and corrupt our educational system worldwide. Once it has been corrupted and dismantled from a global perspective, society will fail to exist.

KEY TERMS AND DEFINITIONS

Academic Cheating: An individual who does not utilize their own intelligence to give their interpretation of the content.

Cybercriminals: Individuals who commit crimes via the internet.

Fraud: A practice or series of acts that are designed to take advantage of individuals, systems, or other process for the benefit of someone else.

Ghostwriters: Individuals who conceal their true identities from detection by engaging in schemes intended to defraud.

Integrity: Being whole and having a consistent set of ethical, moral, and legal practices.

Paper Mills: Business entities created for the sole purpose for selling scholarly works and publications written by ghostwriters.

Plagiarism: Individuals who intentionally create and publish false information to gain an advantage or benefit.

Modus Operandi in Cybercrime

INTRODUCTION

Every person has their own way of doing something, from simple-to-interpret routinized actions to significant acts, which are difficult to observe. Even though we are not aware of it most of the time, we often recognize our counterparts opposite because of their *modus operandi* before we can see their face. This “particular way or method of doing something” (English Oxford Living Dictionaries, n.d.) is called the *modus operandi*. Behind this term lies a vast and heterogeneous field of definitions and interpretations. Especially in the context of crime studies, the *modus operandi* represents an important concept to learn about offenders. This concept is used to raise the existing knowledge about the defendant and his/her approach to criminal activity, in order to predict, prevent and deter future crimes. While analysing the *modus operandi* is already well-established practice used to detect offenders in traditional forms of crime, it is not yet commonly used in cybercrime. The most important reason is the lack of insight into the approach of a cybercriminal. His/her playground is cyberspace, where it is difficult to gather all the details needed to construct a complete picture of a *modus operandi*. This difficulty arises because not all data in cyberspace is easily accessible, and even criminals with basic technical knowledge can hide themselves and camouflage their activities without much of a problem. Hence, this lack of insight leads to a lack of knowledge about the activities perpetrated before the victim recognizes the damage.

In this article the concept of *modus operandi* will be discussed within the context of the phenomenon of cybercrime. In the first chapter, the terms cybercrime and *modus operandi* will be defined. In the second chapter, the article will explore the nature of cybercrime as a topic situated at the interface of different disciplines. In particular, the challenges and topics of the three most important disciplines will be outlined. When talking about the idea of *modus operandi* in the context of cybercrime, technical aspects that represent the framework conditions warrant further consideration. The third chapter of the article will examine these in two steps. First, the technical aspects of the *modus operandi* concept in cybercrime will be set down. Next, different classifications of potential criminals will be discussed

DOI: 10.4018/978-1-5225-9715-5.ch013

and one classification type selected as an example of how the *modus operandi* in cybercrime could be analysed. In the closing chapter, the authors make recommendations concerning the need for greater awareness, knowledge, prosecution, and cooperation, and argue for the necessity of future research.

One of the objectives of this article is (1) to illustrate that valid definitions of cybercrime and of the *modus operandi* have to take the interdisciplinary nature of both concepts into account. The second objective is (2) to highlight the issues and challenges the various disciplines have to face when talking about cybercrime. This article will continue (3) with an explanation of what a *modus operandi* in cybercrime could look like in practice. This will be achieved through the use of different studies that developed a classification of the motivation of cybercriminals, with a focus being on a recent study of defendants in Austria. Last but not least, the aim of this article is (4) to present recommendations and a conclusion pertaining to the key issues to be kept in mind when talking about the *modus operandi* in cybercrime.

BACKGROUND

Before addressing the topic in more detail, the basic terms of this article, namely “cybercrime” and “*modus operandi*” will be defined as follows.

Defining Cybercrime

Researchers from all disciplines commonly understand cybercrime as a sort of crime that involves, uses or is related to the computer or to information technology (Furnell, 2003; Varghese, 2016; Wilson, 2008). “Cybercrime differs from crime primarily in the way it is committed: Criminals use guns, whereas cybercriminals use computer technology.” (Brenner, 2010, p. 10)

The most basic distinction in defining cybercrime can be made by splitting it in two categories, “computer-assisted cybercrime” and “computer-focused cybercrime” (Furnell, 2001). This distinction has been made by various researchers from different disciplines. While Furnell (2001) characterizes the terms as already mentioned, Gordon and Ford (2006) critically discuss “Type I” and “Type II” cybercrime. McGuire and Dowling (2013) call their categories “cyber-dependent crime” and “cyber-enabled crime”. The United Nations (2000) makes the distinction between “cybercrime in a narrower sense” and “cybercrime in a broader sense”, while also conveying the same core meaning as the terms used before.

1. Computer-focused cybercrime, Type I cybercrime, cyber-dependent crime, cybercrime in a narrower sense:

This type of cybercrime relates to offences that can only be committed online. These offences do not exist offline in any way; they occur within the confines of cyberspace. This type of cybercrime includes the violation of confidentiality, integrity and availability of networks, as well as of devices, data and services connected within these networks. Examples for this type of cybercrime range from the spreading of malware to hacking, and attacks on network infrastructure or websites.

2. Computer-assisted cybercrime, Type II cybercrime, cyber-enabled crime, cybercrime in a broader sense:

Cyber-enabled crime refers to cybercrime in a broader sense therefore extending the definition to include traditional offences which have moved from real life to cyberspace. These offences have existed long before cyberspace itself, but have increased in terms of their scale or reach when perpetrated in cyberspace. Typical examples of cyber-enabled crimes are fraud (such as phishing or online banking frauds), theft (especially identity-theft), virtual sexual offences against children, and cyberstalking.

Psychologists Kirwan and Power (2013) have suggested the existence of a third type of cybercrime, the so-called “crimes in virtual world”. This term refers to events that happen between online virtual characters like avatars, and constitute acts that would be counted as criminal offences in the offline world. Examples include murder, theft, sexual assault or physical violence. They moreover suggest another nuance to the definition of cybercrime, relating to the objective of the attack. They differentiate cybercrime into “property crime”, like identity theft and fraud, and “cybercrime against the person”, for example cybercrime involving the sexual abuse of children. This enhancement is similar to the one made by Clough (2015), who discusses cybercrime from a legal perspective and makes a distinction between different offences based on whether the computer is the target, if the offences are fraud-related, content-related (e.g. child pornography), or offences against the person. While the category computer as target is directly comparable with the computer-focused cybercrime, the existence of other categories implies the need for a more detailed classification of computer-assisted cybercrime.

Defining Modus Operandi

The “English Oxford Living Dictionaries” define the term *modus operandi* as “a particular way or method of doing something”, stating that “every killer has his own special *modus operandi*” (English Oxford Living Dictionaries, n.d.). Further, the Merriam Webster Dictionary refers to the concept as “a method of procedure” or especially: “a distinct pattern or method of operation that indicates or suggests the work of a single criminal in more than one crime” (Dictionary by Merriam-Webster, n.d.). The well-known sociologist Pierre Bourdieu (1976) coined the term “*modus operandi*” as part of his Habitus concept. He understood the *modus operandi* as generation principle of the Habitus, whereby the term therefore implies the constituent structures which cause the habitual structures. The *modus operandi* can therefore be seen as the guiding principle according to which forms of practice and schemes are created. However, an observing scientist can only perceive and analyse the results from evaluations and from thinking schemes: the “opus operatum”. Here, the *modus operandi* remains hidden. According to Bourdieu, however, scientific analysis must go further and try to understand the production principle of practice - the *modus operandi* - apart from the empirical observation of the products. Following Bourdieu, researchers from different disciplines tried to define *modus operandi* (De Wet, Labuschagne & Chiroro, 2009; Hazelwood & Warren, 2003; Bennell & Jones, 2005). In most cases, these researchers discuss an offender’s *modus operandi* in the context of traditional crimes like burglary and rape. The *modus operandi* concept is therefore often employed as a means of linking crimes based on behavioural information as alternative to physical evidence (Bennell & Jones, 2005).

The concept of *modus operandi* in relation to cybercrime describes the perpetrator’s approach to committing a cybercrime offence. This includes the consideration and planning of a crime in advance, as well as actual preparations, and all stages of the crime and post-processing such as the removal, concealment and blurring of traces. The identification, documentation and analysis of the *modus operandi* behind criminal activities in cyberspace is therefore of central significance to understand how cybercrime works and which principles it follows. This includes the identification of goals, targets, motivation and attack patterns as they unfold. Casey (2008) and Turvey (2011) are some of the first researchers to discuss the

relationship between the concept of *modus operandi* and technology. They mention that computer and internet-related technologies are used in different stages of criminal activities and therefore need closer analysis. Moreover, they also discuss methods by which technology could support the determination of a *modus operandi* in traditional crime cases. Some authors have already created different typologies of cybercriminals, based on their *modus operandi* (Casey, 2008; Furnell, 2001; Ngafeeson, 2010; Turvey, 2011). These categorizations differ in their focus between technical issues, the victim, motivation and objective of the offender and further distinguishing factors.

A TRANSDISCIPLINARY PHENOMENON

Cybercrime is a phenomenon that is located at the intersection of different disciplines. On the one hand (1) cybercrime on its own is an in-depth technical topic concerned with objectives as well as the approach taken of cybercrime. Moreover, cybercrime is (2) a crime against the law and therefore the topic is of great legal and criminological importance. Additionally, cybercrime is (3) a consequence of the relocation of our living space into cyberspace and the associated influence this has had on our actions - thus a social or sociological topic. With a special focus on the *modus operandi* in cybercrime, we need to bear in mind the influence of several other disciplines, i.e. media studies, psychology and economic while analysing offenders and victim's behaviour. This diversity across such a variety of disciplines clearly results in the necessity of a transdisciplinary approach in dealing with the phenomenon of cybercrime. In this section a short insight into the basics of the three most fundamental disciplines when talking about cybercrime will be given. The section will show the common concepts and challenges of these disciplines.

Technical Studies

Several institutions and agencies have tried to develop specific classifications of cybercrime from a more technical perspective, for example the Computer Security Institute (2001) and Europol (2018). While such classification attempts are valuable and necessary, rapidly developing new and disruptive technologies lead to this becoming a moving target. With every new technology come new ways of exploiting it and new approaches for countering these methods have to be developed. Therefore, a more fundamental approach, aimed at identifying the general method of attack applied by cyber criminals, is required. The Cyber Kill Chain® framework developed as part of the Intelligence Driven Defense® model for identification and prevention of cyber intrusions activity by Hutchins, Cloppert and Amin (2010) is a good example of documenting the approach of the offender from a technologically oriented process perspective, including possible counter measures. While this model is primarily aimed at combating advanced persistent threats, it can serve as template for dealing with cyber-attacks that are more sophisticated.

While in the past cyber-attacks depended on a criminal having a certain level of knowledge, this barrier has been considerably lowered by cybercrime now being offered as service (otherwise known as CaaS). Worrying analyses documented in the latest report from the Internet Organised Crime Threat Assessment (Europol, 2018) point towards an increasing “upstream trend”, i.e. cybercrime tools being offered as CaaS turning into a significant problem. The most worrying trend on the horizon is the ease of availability of military grade attack technology to criminals, which might soon include such advanced components as big data analysis or artificial intelligence modules for planning and carrying out cybercrime. Depending on the accessibility of technology for cyber criminals, their approach will continue to adapt and evolve,

as could already be seen during the different waves of ransomware attacks in spring and summer 2017 (Europol, 2018). A current strategy to defend against advanced forms of attacks is the concept of cyber threat information sharing: “Threat information is any information related to a threat that might help an organization protect itself against a threat or detect the activities of an actor.” (Johnson et al., 2016, p. 2) According to Johnson et al. (2016) there are different types of threat information including indicators of compromise (IOCs) as well as tactics, techniques, and procedures (TTPs) used by threat actors, security alerts, threat intelligence reports and recommendations for tool configurations. To gather this information about the threat, it is necessary to scan potentially affected systems for the presence of unusual artifacts (software and data) and to detect unusual system behaviour (i.e. IOCs). That is why a significant step forward is expected from the introduction of machine learning and artificial intelligence techniques when it comes to the detection and identification of IOCs and associated emerging patterns that characterize certain forms of cyber-attacks. Burnap et al. (2017) for example used machine activity metrics with the aim to distinguish between malicious and trusted software samples. By doing so, they developed a new classification method using self-organizing feature maps.

Law and Crime Studies

“*Modus operandi* is a characteristic pattern of methods of a repeated criminal act, used to identify the culprit.” (US Legal, n.d.) This definition already shows the greatest challenge for the law studies regarding an international view on the topic cybercrime: The question of what a criminal act is will be answered very differently depending on the jurisdiction and cultural background of a person, and also the context of an action in cyberspace. The process of prosecution is additionally more complex because of different topics such as the problem of handling digital evidence and the security vs. privacy debate, to list some of the core issues. In general, legal scholars – when talking about the phenomenon of cybercrime – focus primarily on discussing national and international strategies and legislation regarding cybercrime.

In recent years, a great majority of nations have introduced a cybersecurity strategy, which can be looked up on the website of the NATO Cooperative Cyber Defence Center of Excellence (2015). Based on these strategies, a comparative analysis has disclosed six principles that can be found in all security strategies: Maintenance of existing fundamental rights and national values, disclosure of responsibilities and legal framework conditions, establishment of security and resilience of ICT systems, promotion of national and international cooperation and coordination, raising awareness and skills as well as promoting research and development, securing economic success and advantages (Pospisil, Gusenbauer, Huber, & Hellwig, 2017). The principle “disclosure of responsibilities and legal framework conditions” shows the great importance of this topic for nearly all nations. Major players like the USA (The White House, 2011), the EU (European Commission, 2013) and the United Kingdom (Cabinet Office, 2011) highlight the necessity for international prosecution and the international harmonization of the law with regard to cybercrime. Therefore, the Convention on Cybercrime (Council of Europe, 2001) constituted a significant milestone, as it was the first international agreement addressing the harmonization of national law pertaining to cybercrime. Within this convention, the member states of the council of Europe and other states agreed on necessary steps to develop international legislation as well as cross-border cooperation. Nevertheless, while some nations have enacted laws specifically directed towards cybercrime, others rely on applying existing law that deals with traditional acts of crime. From a truly international perspective it could be said that 72% of all countries have legislation regarding cybercrime, 9% have a draft legislation on the topic, and 18% do not even have legislation at all (United Nations Conference on

Trade and Development, n.d.). Although the exact legal situation depends to great extent on the nation itself, nearly all try to address four problem areas that cybercrime offences have created: the protection of privacy, the prosecution of economic crimes, the protection of intellectual property and the procedural provisions to aid in the prosecution of computer crimes (Pelker, Palmer, Raia, & Agosti, 2015).

Different authors of law studies discuss legal issues pertaining to cybercrime with a national focus. While Cartwright (2016) discusses the complicated nature of cyberspace, which is both a public and private space, Brenner (2004) concludes that the United States federal cybercrime law needs more provisions to protect the privacy of individuals. Moreover, the difficulties inherent in investigating cybercrime are numerous, and range from the national as well as international consistency of legislation, investigation and prosecution (Mohammed, Mohammed, & Solanke, 2019; Haase, 2013) to the complexity and volatility of digital evidence (Schwerha, 2004). Carter (1995), an US-based researcher, provides recommendations to improve law enforcement, which could also suit various other states “Protocols must be developed for law enforcement that address [sic] the various categories of computer crime. Investigators must know the materials to search and seize the electronic evidence to recover, and the chain of custody to maintain.” (Carter, 1995, p. 26)

Sociology

While technical studies focus on the “cyber” element of cybercrime, and legal studies on “crime”, sociology focusses on the societal factors involved in cybercrime. From a sociological perspective cyberspace basically is - to concur with Schütz and Luckmann (2003) - an expansion of the “Lebenswelt”. The “Lebenswelt”, a complex concept first introduced by Edmund Husserl (1976) and elaborated by Schütz and Luckmann, refers to the totality of the possible horizon of experience of the members of the society. As the offline world is supplemented by the online world, numerous new platforms emerge, each of them having their own norms, values and forms of behaviour (Geser, 2002). In the context of these new spaces, Geser (2002) talks about “vireality”; the phenomenon whereby the “real” character of an individual may be more genuinely expressed in its “virtual” role than in its real-world identity.

Sociologists commonly gain knowledge related to offenders, victims and attack-types as well as about prevention, technology assessment and long-term consequences. The major challenges they face are the anonymity of the cybercrime offender and the large number of cyberattacks that remain undetected or unreported. Broadhurst et al. (2013) analyses the role of organized crime groups in cybercrime. They illustrate three different types of groups: Type I – these groups operate essentially online, Type II – these groups combine online and offline offending, Type III – these groups operate commonly offline with the support of online technology. With reference to the victims of cybercrime, it is possible to talk about two major types: private persons and institutions (Huber et al., 2018). While private persons often become victims because of the exploitation of a trust relationship, institutions are often victimised due to the exploitation of a technical vulnerability. Varghese (2016) however creates a classification of 13 different types of cybercrime offences. Some of them, for example hacking and cyberstalking, receive focused attention from other researchers in the field of social science. Jordan and Taylor (1998) try an early characterization of a hacker by discussing specific principles. Their aim is to question the current picture of a hacker. Another facet of cybercrime is the phenomenon of cyberstalking. This is the obsessive harassment or threat via digital media, which has increased in recent years. More and more private individuals are becoming victims of digital acts of revenge. These can be carried out by private or professional perpetrators (Huber, 2013).

Various researchers from social science (Ogbuaja, 2016; Seböck & Pospisil, 2016; Varghese, 2016) speak out for the necessity to raise the societal awareness of cybersecurity and cybercrime, including an expansion of training programs regarding these topics.

MODUS OPERANDI IN CYBERCRIME

Technical Aspects

Cybercrime depends on the exploitation of vulnerabilities in an organization's or a person's ICT system. While attacks might first become visible through social engineering, i.e. the exploitation of human weaknesses, the actual cybercrime starts well before with a target reconnaissance phase. Whether aimed at obstruction, distortion, destruction, espionage or extortion as the preeminent goal of the cyber-criminal, planning the crime and collecting information about the victim is usually the first step, which is definitely helped by a wide range of information being available on social media, through search engines, and ultimately through web services operated by criminals. While in the past this required considerable effort, the emergence of the so called crime as a service (CaaS) has led to this and further steps of a criminal operation being offered in a way similar to web services through online market places operated by criminals who produce or modify software tools and offer to carry out cybercrime in the form of a pay-per-use-service. Worrying reports (GovCERT.ch, 2016) indicate that there are basically three major phases in an advanced cybercriminal operation: the initial target evaluation and target reconnaissance, the attack planning and weaponisation phase, followed by the actual infiltration and attack delivery. New technological developments, primarily artificial intelligence and big data analytics might soon be added to the already existing set of attack tools. While effective countermeasures are available against malware, ransomware, denial of service and some forms of advance persistent threats, the combination of these attacks with the new technological capabilities will render them far harder to prevent and counter. With regard to the already high sophistication of CaaS and emerging technological trends, it can therefore also be assumed that the defence against cybercrime must start from a comparatively high level, such as the Cyber Kill Chain® framework (Hutchins, Cloppert & Amin, 2010), which has become a standard reference since its introduction. Technology becomes increasingly sophisticated and powerful and so does its vulnerability, as can be seen in the case of IoT. Old forms of attacks will therefore also continue to exist, trying to make use of new vulnerabilities and exploiting new environments (Kolias, Kambourakis, Stavrou & Voas, 2017).

To gather information about the *modus operandi* of a cybercriminal it is a common method to describe his/her behaviour with the concept of tactics, techniques, and procedures (TTPs). By doing so, it is possible to determine a cybercriminal's tendency to use, for example, specific operations, attack tools or exploits (Johnson et al., 2016). The ATT&CK model (Adversarial Tactics, Techniques, and Common Knowledge) developed by MITRE 2015 goes a step further and allows for the process modelling of post-compromise adversary behaviour (Strom et al., 2017). This means, that the model focuses on the behaviour of the attacker after he/she got access to a system within a network. To do so, the model presents seven steps of action: identify behaviours, acquire data, develop analytics, develop an adversary emulation scenario, emulate threat, investigate attack and evaluate performance. Moreover, the model is open access for everyone, and hence functions as a globally accessible knowledge base.

Classification of Defendants

When analysing the *modus operandi* in cybercrime, it is common to take a closer look at the defendant regarding different variables. Thus researchers ask for the motivations of the defendant; the approach taken, as well as the way the victim is chosen and the choice of vulnerability used to enter the system. All this information helps illustrating different *modi operandi*, which can focus on a very precise type of defendants or can be more general.

Turvey (2011), for example, outlines six very general types of behaviour, each of which should cover the different types of crime offences: Power Reassurance, Power Assertive, Anger Retaliatory, Sadistic, Opportunistic and Profit Oriented. While some of these concepts sound conclusive, they seem not to suit well for the special topic of cybercrime offences. In contrast, Casey (2008) puts forward a very special classification, and differentiates eight motivational categories of critical information technology insiders: explorers, good samaritans, hackers, machiavellians, exceptions, avengers, career thieves and moles. Furnell (2001) presents seven motivations that a defendant could have: Challenge, Ego, Espionage, Ideology, Mischief, Money and Revenge. Based on these motivations he differentiates between nine types of defendants: Cyberterrorists, Cyber Warriors, Hacktivist, Malware writers, Old School, Phreakers, Samurai, Script Kiddies, Warez D00dz. When looking at these motifs, Furnell's (2001) results show significant similarities with the latest evidence-based classification developed by Huber, Pospisil and Seböck (2018) based on cybercrime offenses prosecuted at the Vienna Criminal Court between 2006 and 2016. The results of this analysis show that there are five different types of defendants, separated by their motivation: Revenge Crime, Financial Crime, Show-off Crime, Conviction Crime and Follower Crime. The analysis from Huber, Pospisil and Seböck (2018) identifies two typical patterns of cybercrime cases that could not be solved. These two patterns can be identified, as the literature suggests, in computer-assisted and computer-focused cybercrime:

- Computer-assisted cybercrime
 - Type I: Revenge crime
 - Type II: Financial crime
- Computer-focused cybercrime
 - Type III: Show-off crime
 - Type IV: Conviction crime
 - Type V: Follower crime

The types differed from each other not just in their motivation, but also in their approach, the way in which they chose their victims and the damage they caused. In the following, the motivational types will be illustrated briefly based on these variables and case examples. Before this, it has to be noted that the authors made the conscious decision to focus their data collection on general paragraphs of cybercrime. They therefore did not include special paragraphs of child pornography and hate crime or radicalization. This decision was based on the legal framework and the different paragraphs underlying these offences. While this analysis focuses on classical paragraphs of cybercrime, the study of child pornography offences and hate crimes like radicalization requires an examination of completely different paragraphs. Moreover, the authors follow the assumption that these content-related cases are very different from other cases of cybercrime. For this reason, it can also be assumed that the motives behind offences of child pornography and hate crimes differ from those mentioned here.

TYPE I: REVENGE CRIME

After a jealousy dispute, B separates from A. A is upset and wants revenge. Due to the former trust relationship, A knows the password that B uses for different online accounts. A can now access B's Facebook and email accounts without any problem. Once having accessed the accounts, A changes the password, views private data, deletes and modifies it or posts degrading texts and photos in B's name.

Defendants of the type *Revenge crime* commonly operate alone and usually do not have any substantial technical know-how. The defendants often act out of a love relationship that experienced a crisis. Thus the victim is generally a private person, and the attack a targeted one. The defendant usually takes a simple approach and uses the insider knowledge that he or she acquired in the context of the trust relationship against the victim. Veiling measures are not used. In cases of *Revenge crime*, the vulnerability is commonly the naivety and unawareness of the victim. In most of the cases, the offence is a data breach or an attack on networks. The consequences for the victim are usually mental harm and the loss of information.

TYPE II: FINANCIAL CRIME

A wants to make quick money and instructs B to construct a Trojan. Afterwards A logs into a public online chat and pretends to be a young girl searching for a boyfriend. C shows interest and the two soon start a private chat. Pretending it is a photo of "her", A sends a file to C. C opens this file, which in reality contains the Trojan. A can now – with the help of the Trojan – take over the computer in front of C's eyes and extorts C with the private data A now has access to.

Defendants of the type *Financial crime* usually operate in groups, and possess at least basic technical know-how. The approach taken is pretty simple, but the defendants also use basic cover-up measures such as wrong IP addresses to protect themselves. Usually these defendants search for an open vulnerability, so the attack is not targeted. In the cases of the type *Financial crime*, the defendant commonly has no relationship with the victim, who is in the majority of cases a private individual or a company. The vulnerability typically exploited by the defendant is the unawareness of the victim. Common mistakes include the use of very simple passwords and the free disclosure of confidential information by mail, telephone or other communication channels. As with the type *Revenge crime*, the common offences are data breaches or attacks on networks. Typical examples of such acts are phishing attacks and social engineering. After the attack, most victims suffer from financial damage, especially reinstatement costs.

TYPE III: SHOW-OFF CRIME

A is part of a hacker group. Together with some of his friends, A wants to show off his technical skills. They go through the critical infrastructure searching for vulnerabilities and finally find one in authority B. They launch a SQL injection and a Distributed Denial of Service attack on B. Thus, the group modifies and corrupts sensitive data. Finally, they post their attack- information about the vulnerability and the sensitive data - online to publicise their success.

As the case example shows, the defendants of the type *Show-off crime* commonly act in groups of more than two, and have technical skills that they want to show off. The defendants are typically younger and have a rather complex approach to cybercrime as compared to the defendants of the other motivational types. The defendants use camouflaging measures like the TOR-network or VPN-encryption to avoid

detection. The attack itself is often based on tools, but could also be a D(D)oS-attack. Nevertheless, defendants of this type usually search for vulnerabilities, which can also be done technically using a vulnerability scanner. Thus, the offence is not targeted and the defendant usually has no relationship to the victim. In most cases, the victim is an authority or a company and has to face reinstatement costs as well as the loss of reputation and information.

TYPE IV: CONVICTION CRIME

A is a member of a religious perpetrator group. The members of the group are convinced of their radical conviction and want to spread it to find new followers. A uses technical attacks to gain access to the homepage of B. After that A deletes the previous contents of B, and instead displays images of Djihad fighters with machine guns. Messages from the perpetrator group are also left in Arabic script.

Defendants of the type *Conviction crime* usually act in conjunction with accomplices who hold the same conviction, they want to spread. The complexity of the approach is very different and so is the technical know-how of the defendants. They commonly attack homepages of private persons or companies, in most cases to display radical appeals and prohibited content. Thus, the defendants of the *Conviction crime* choose their victim according to the degree of open vulnerability, and do usually not have a relationship to them. The victims suffer from the loss of information as well as the loss of reputation as result of radical content being present on their homepage.

TYPE V: FOLLOWER CRIME

A is very interested in technology and is therefore a participant in a few hacking forums. One day other participants brag about having cracked B's system and post instructions, vulnerabilities and sensitive data in the forum. A is curious and tries out the instructions. A gets access to B's email account, reads the emails and changes the password.

The offences of the type *Follower crime* need an enabler that is often found in the type Show-off crime. The defendants of this type of cybercrime either use existing information about vulnerabilities out of a lack of awareness and understanding that they are already committing a crime, or do it consciously out of curiosity. Thus, their approach is very simple and they do not need any technical know-how but have to participate in hacking forums or communities. The attack is not targeted and the defendants usually do not have a relationship with the victim, who could be anyone who was the victim of the enabler in the first place.

SOLUTIONS AND RECOMMENDATIONS

This contribution has so far shown that cybercrime and especially *modus operandi* in cybercrime, is a very diverse phenomenon that has to be considered through the lens of different disciplines and perspectives. Although the gathering of information about the *modus operandi* of offenders is a step in the right direction, there is not just one easy solution for the challenge of creating a safe and secure cyberspace. Nevertheless, some fundamental recommendations may be made:

Raising Awareness and Knowledge

As many studies show, a large number of cybercrime offences could be avoided if victims are made aware of nature of criminal activity online. Therefore, this recommendation has two main objectives: On the one hand, it is necessary to raise society's awareness, as anybody could become the victim of cybercrime, everyone should be prepared to reduce those risk factors within their control. On the other hand, to handle this complex topic, it is equally necessary to raise the knowledge people have regarding the technological, legal, and sociological aspects of this phenomenon. Therefore, it is necessary to anchor the topics cybercrime and cybersecurity in the education system (Jansen et al., 2017).

Improve Prosecution Through Knowledge and Cooperation

Connected to the first recommendation is the need to raise cybercrime conviction levels. Currently, it may be said that, in the context of the prosecution process, convictions are low as there is a huge lack of knowledge about cybercrime as a phenomenon. It is necessary to adequately train the stakeholders in this process – mainly the police, the prosecuting authority and court officials – so they are able to gain important information to support the investigation process (Huber, Pospisil, & Seböck, 2018). In order to deal with the challenge that cybercrime offences do not stop at national borders, it is also important to extend international cooperation in the investigation process (Rashkovski, Naumovski, & Naumovski, 2015). Only if the investigation is successful a case can be solved and prevention improved. Moreover, better stakeholder training would also lead to new information about the *modus operandi* of cybercriminals, gathered from empirical cases that could raise our knowledge about cybercrime as a phenomenon.

FUTURE RESEARCH IN OFFENDER BEHAVIOUR

This is the point where future research has to step in. The study of cybercrime requires more evidence-based analyses concerning the behaviour and *modus operandi* of offenders (Leukfeldt, 2017), as well as of the process of prosecution, in order to improve it. To be successful, future research groups should comprise different disciplines to enable the necessary transdisciplinary view on the topic.

Increase the Attractiveness of Being a “White Hat Hacker”

Last but not least, there is a trend developing that sees more and more talented young people choose a criminal career, and become a “black hat hacker”, over that of an IT-employee, or a “white hat hacker”. The reasons are numerous, and range from personal feelings like curiosity and boredom to the wish for power, peer-recognition and political participation (Madarie, 2017). Law enforcement agencies also have to think about possibilities to increase the attractiveness of becoming an IT-specialist.

Future Research Directions

As already mentioned, future research is going to be very important when it comes to a better understanding of cybercrime. For instance, dark field analysis could be a way to gather new information and raise the knowledge about the *modus operandi* of offenders in cybercrime. The research and application

of developments in the field of *modus operandi*, therefore, requires new methods and potentially new ways of thinking.

Future research on the *modus operandi* in cybercrime could take two directions:

1. While cybercrime is on the rise, the impact of the offences increases and affects more and more disciplines. Therefore, the topic becomes even broader and more interdisciplinary. Here research teams, in attempting to develop the topic try to cover as many disciplines as they can to illustrate this complex phenomenon. The core challenge hindering the development of platform or system in such a situation would be the lack of clarity because of the endlessness of impacted disciplines.
2. As cybercrime is at its core a technical topic, it is obvious that there is a need for tools aimed at a technical way to analyse the *modus operandi* of offenders. However, it is still an open question whether artificial intelligence combined with big data analytics will be able to deliver such a tool.

CONCLUSION

The *modus operandi* constitutes much more than just another cybercrime topic. Understanding the concept could be the key to answering the question of whether in future we will be able to strengthen the defence against the offence. Currently, there is an imbalance of power between attacker and defender, because attacking a system is always easier than keeping it safe. A better grasp of the *modus operandi* concept will make it is possible to deepen the understanding of the offender and thus improve prevention and reaction. To conclude, while much about the *modus operandi* of cybercriminals still remains in the dark, two core elements for successful cybercrime prevention may be identified: First, the recognition that fight against cybercrime affects everyone, because anyone could become a victim, and we need to realize that. Second, in order to win the fight against cybercrime, a more nuanced awareness of the way in which cybercrime works is necessary to both predict criminal use of technology, and to put in place timely preventive and forensic counter measures that protect individuals and organizations or (in an ideal case) deter potential attacks.

INTRODUCTION

The triad of education, human development and socio-economic transformation or otherwise is central to the understanding of the processes involved in the workings of modern society. Inadvertently, the cyclical relationship existing between these three has been documented in research (Virginia, 2005; 27). Of recent, education was described as one of the accelerators of human, social and economic development (Ifenkwe, 2013:007). The importance of education remains unquantifiable across major indices of socio-economic development. Fundamentally, education promotes mastery of some certain procedures to the point where they become unconscious and automatic, it also permits the application of the procedures to structure information into conceptual knowledge that is used consciously and deliberately (Abadzi, 2006). These attributes when put together make education unique in its contributions to relational advancement globally.

Traditionally, education serves as a potent instrument for eliciting conformism to institutional rules and regulations and men in their various classes are socialized with the view of sustaining social stability and progress. However, in modern society, a subset of deliberate educational application tilts towards the retardation of development in the context of actions that are inimical to the overall interest of the generality. Few occurrences in the technological age attest to the fact that educational application is not uni-lineal in its consequences for socio-economic development. Of a truth, there is a dual application of educational inputs and with its negative connotations unabatedly becoming registerable in crime and in

a gamut of other anti-social behaviours globally. The manifest function of education that is commonly ushering and sustaining this turn of event is not farfetched. At inception, the defect of working against the interest of significant individuals and favouring few others has been the bane of education. This was aptly described by Coffey (2001) as differential outcomes of education.

In educational acquisition, the key democratic ideals of liberty and equality have always been in conflict in a nation with acute capitalist acumen (Brantlinger, 2007). Explaining this in a concise manner, Deleuze and Guattari (1983) disclosed that the emergence of monopoly capitalism radically transformed the social world: it swept away traditional social forms, as economic forces bite deeply into the symbolic textures of society itself (cited in Elliot, 2014:255). This symptom of destabilization then became recordable in the negativity attendant to educational skill utilization. Noblit and Pink (1995) argue that whereas the original philosophy for schooling hinges on achieving consensual relationship among diversely attributed populace, recent experiences have clearly shown that schooling is consistently promoting opposition, resistance and conflict in its consequences for societal survival. Apart from the factor located in biasness and inferiority attendant of diverse mode of knowledge dissemination according to Bourdieu, (1984), the unraveling scenario in the information technology age has now shown that school dropout is no longer sufficient reason for youth crime participation in the modern era. More significantly is the continued access of the vast majority of people to e-technology gadgets with its concomitant transformation of a relationship into virtuality.

E-relationship promotes the subtle quest for additional education enlightenment for its operability. Just as it were, more and more techno-elites have been drawn into the manipulation of the arena for both licit and illicit gains. More education now tilts to more crime involvement promoted by the increasing opportunities potentially offered by the virtual technologies and its environment. Consequently, this paper attempts to refocus attention to the changing trend in education and crime nexus. A departure from the hitherto paradigmatic leaning in criminology on less education more crime and substantial education, less or non-crime is gradually stirring one at the face (Miller, 1958; Moffitt, 1990; Farrington. 1992). Paradigm, as explained by Brown, Esbensen and Geis (2013:19) represents a tool that provides a general orientation to explaining and understanding crime as a phenomenon. With more and more of human activities booking their places in the cyberspace, so also is the increased yearnings for functional education to meet the demands of today virtual technological society across all facets of legal, semi-legal and illicit organs of the global community. Hence, the advocacy of this discourse is to cause an arousal on the changing trend in the theoretical fundamentals underpinning education and cyber-crime participation while using the evidentiary data collected from a youth study conducted in Lagos, Nigeria.

THEORETICAL FRAMEWORK

There is a gamut of issues propelling people into crime in modern society. Criminologists both in the classical and contemporary times have blamed culture, social structure and the economic system on the prevalence of crime (Conklin, 2007:149). Considering the various existed ideological variables on crime instigators therefore, two theoretical viewpoints become central to the basic argument of this research. First, Merton's social strain theory is appraised as relatively representing contemporary thinking in education-crime affinity while the classical discourse of Quetelet arouses and intensified our knowledge base on the affinal between the acquisition of qualitative education and virtual crime participation in the era of modernity. The concern of the latter remotely captures the hub of the argument of this research. Besides the philosophical leanings of both theory, their adequacy in time and space is basically reinforced by their

explicatory capacity in the technological age (or otherwise) and thus instigating the re-examination of the intellectual values of several extant theories that are mostly reducing crime events to the deficiency in educational acquisition. Currently, most hitherto known ideological landmarks across social science disciplines are confronted with the herculean task of achieving predictive exactness at the level of both intellectual, social, economic, political and canonical planes and this is as a result of the magnitude of change that has impacted the existing global society. Besides, more intriguing are the developments in the technological age that are basically challenging most hitherto existed knowledge in crime studies.

The process of economic development which paved the way to technological boom affects the nature, complexity, amount and characteristics of crime in circulation in modern society and thus querying all known boundaries of crime explanations. For instance, within the structural tradition of crime causation, the known theoretical explanation affecting education and crime involvement presents a symbiotic relationship experientially today rather than the inverse relationship formerly reported before the advent of ICT age. A notable scholar in the structuralist tradition, Merton (1938), expressed the view that the occupation of disadvantaged position in the social structure conscripts' the ability of youths in the lower-class category to achieve success through the socially approved means such as hard work, formal education and thrift. The inability to achieve success through these variables according to Merton becomes a precursor of crime. More education in this wise connotes less strain and little or no push into crime. In fact, goal displacement for individuals as a result of insufficient education becomes a potent stressor that will be followed by crime related activism. However, contrary to this initial observation, there is an unfolding scenario in recent times consistently exhuming the findings of past research and situating the findings of same as the most ideal construct needed to capture developments that are unraveling in today crime environment. This is located in the findings of a study conducted by Quetelet "Of the Development of the Propensity to Crime" (1842/2013) where he referred to crime instigators as the propensity to crime. He was the first classical criminologist to notice in France that there exists a correlation between the level of intellectual state and involvement in crime. Basically according to him, the higher or developed the intellectual state of a criminal, the more complex is his/her involvement in crime. (Complexity in this regard focusses on the manipulative capacities of would-be criminals). Criminals in this category are empowered or enabled to undertake complex criminal tasks requiring sophisticated processes, achieve more successes and capable of covering up crime leads. However, taking a skeptical look once again at this discovery, Quetelet expressed a dilemma on whether knowledge acquisition is injurious to human society. As a matter of fact, the "enlightened classes" (intellectuals, highly educated, wealthy) were hitherto presumed to possess more affluence and are less frequently under strain and without the necessity of having recourse to crime. Summarily, occupiers of this statuses were accounted as insulated from the push and pull of crime.

Experiencing a reverse order, one should rarely know that this position is rife in criminological theorizing until recent times when the world began to harvest new modes of crime. Despite the existence of this presumed chance, Quetelet, juxtaposed that affluence and educational knowledge have not an equal power in subduing the fire of the passions and sentiments commonly found among humans which is basically conditioning man toward hatred, greed, self-centeredness and vengeance. In a way, the acquisition of more education is not suppressive of human frailty in working contrary to societal morality. To support his findings, Quetelet engaged a comprehensive classification and analysis of crimes committed by several categories of suspects within nine hypothetical classes he created from the data collated in France from 1828-1829. Reporting on the result of the analysis, he pointed out the fact that those who are supposedly educated when duly compared with their counterparts who are adjudged less educated committed more crimes in relation to persons. This exposition in literature is in consonance

with the observation of this study. Borrowing from this view, therefore, it is interestingly to examine the influence of the intellectual state of the accused or suspects on the nature of crime pervading the virtual environment today, which represents a feat that is not a total departure from what was earlier identified by Quetelet. While in the traditional society, crime committed by those regarded as enlightened or knowledgeable were often dismissed as chivalry, this is no longer the case today. Then in the primitive societies, princes, knights and the Royals (purported to be educated) engaged the physical plundering of property and subjugated relatively non-enlightened citizens and folks residing within and those external to their domain through the use of wars and ideologies for the purpose of survival and amazing wealth. Conversely, the forms of technological driven crimes of modern society are more directed against persons rather than property. This dimension often imposes colossal loss on a myriad of people in the virtual environment. Attacks projected through hacking, information theft, ordered good diversions, online fraud, cyber bullying and stalking etc. are more impactful on people than the vulnerability of property emanating from property crimes. Non-virtual crimes in the traditional, agrarian or early technological society require little or no intellectual acumen for both its operationality and success. Virtual crimes are operable via the foundational structure technical knowledge and supported by depth educational acquisition of would be criminal.

Consequently, in the ICT environment supporting borderless interaction, possession of education skills helps promote both cyber fraud participation, support technical know-how needed to operate in the virtual world and correspondingly guarantees the survival of virtual criminal in the crime environment. The knowledge base of the virtual criminals can be adjudged to be dynamic and versatile when examined from the required skills needed to manipulate the virtual technologies. The only resource that confers this upon the criminal and sustains ICT related crime is education and will remain more education in its future sense. Both theories expounded in this section were found to be complimentary in shunning out ideas require to chat a new theoretical plane in cyber criminality.

LITERATURE REVIEW

In most traditional settings, education is quite central to the acquisition of positive outcomes both at the macro and micro levels of human society. While references were often made to the expected outcomes of education, only relatively few studies engage the negative effects of education on the individual, organization and society. This gap in literature, constitutes the focus of this research paper. The double-edged outcome of education resides in the pattern of educational skills utilization by its beneficiaries (Okafor, Imhonopi and Urim, 2011). It is common knowledge to know that education imparts knowledge and skills related to specific jobs and household management (Croteau and Hoynes, 2013:347). Developmental outcomes promoting affinity between education, the economy, society and life chances therefore has been accentuated in sociology literature (Coffey, 2001; Jegede, Ajayi and Allo, 2016). The trend that appears general in the discursive efforts of scholars of sociology of education involves the realities of educational experiences which carry both positive and negative connotations. At the entry point of these experiences involves the avowed requirements for certification of skills and the increased emphasis on credentialization with constraining effects on aspirations and basically founded on unequal pedestals for potential aspirers. The issue at stake revolving around the aforesaid experiences include challenges relating to access to education, ability to use resources in society and the nature of resources different people have at their disposal and under their direction (Barton and Walker, 2007). And considering the inhibitions derivable from the possession of or lack of these listed variables, several efforts have been

made to establish the relationship between class, pattern of education, accessibility to qualitative schooling, mobility and life chances. While these were viewed as a product of inequality and social divisions inherent in the structure of human population, these attributes also serve as the major determinant of behavioural participation. In this regard, the enactment of either acceptable or non-acceptable behaviours is therefore dependent on the perpetuity or quality time devoted to residing in a class by an individual or group and the class one belonged to is also a function of the quantity of educational acquisition, accessibility to higher paying employment and variability of life conditions of the affected individual or group. Class retention, immobility and behavioural component at any given instance, is often reinforced by cultural reproduction of differences and politics of identity construction attendant to educational experiences.

In recent times, risk factors such as the cloud of economic uncertainty, occupational future and the dire saturation of the labour market account significantly for the changing trends in educational outcomes globally. The devastating effect of this is much more pronounced among the youth due to their peculiarities. In terms of their characteristics, the youths are mostly acquirers of education than the old cohorts and thus exerting formidable pressure on the national economic system. They are also more vulnerable and having higher potentials for victimization in the context of the structural ill of any nation (Cho and Newhouse, 2011; Jegede, 2016). Major dislocation is therefore recordable in the area of being made redundant despite the possession of the requirements for absorption into the economy. Bell and Blanchflower (2010) were quick to report that being unemployed while young can cause permanent scars rather than temporary blemishes, and the potential for long-term damage can be more potent in a recessive economy which is a case akin to the eventful of the current area of study.

The worse scenario linkable to recessive economy is recordable and endemic in Africa and particularly in Nigeria due to the existence of weak institutions and policies that have wasted resources through unbridled official corruption and has consistently damaged living standards and inhibited development (Udoka, 2012; Ayedun, Durodola and Akinjare 2012; Ayedun, et al 2018). As a result, the massive impoverishment attendant to this national catastrophe has occasioned diversity of experiences that are affecting all facet of human life and in the process causing the classification of people into varied capacities in terms of abilities to command choice resources or goods. While few were enjoying the unfolding situation, there are so many people groaning under the burden of economic predicament and thus boxing them into low class with its attendant challenges. The combination of low class status, poor access to education and educational achievement, and inclination to participate in crime have been found to be correlated (Brown, Halsey, Lauder and Wells, 1997). Research has shown that educational experiences have a significant impact on behavioural choices. Importantly, youths who fail at school and eventually dropped out are the ones mostly assumed theoretically to likely engage in criminal behaviour. In this wise, academic performance is a significant predictor of crime and delinquency (Maguin and Loeber, 1996; Siegel and Senna, 2004:68). The philosophy behind this paradigmatic position involves the widely held notion in the academic circle that drop outs are likely to have fewer job prospects, make less money and are more likely to be unemployed (Regoli and Hewitt, 2003:284). Conventionally, therefore, educationally disadvantaged personalities were collectively viewed as having the potentials of participating, perpetrating and persisting in crime and other anti-social behaviour. (This factor is further explained in the later paragraphs of this review).

Asides from the synergy between defective education and crime, there are more concentration of scholars' attention to the evaluation of inequality and the role of cultural politics of education that are basically promoting reduction in access to education and the eventful of deteriorated lifestyles often leading to the adoption of anti-social options, this position notwithstanding, it is here advocated that a shift in factorial analysis of experiential outcomes and the atmosphere of socio-economic conditions

bearing non-anticipated consequences for human life chances be re-engaged to accommodate the unfolding convergence of increment in education credentialization and the corresponding technology crime participation which is soaring by the day. This shift is required to prove or capture how increasingly individuals and groups are coping with the complexities of educational outcomes and their attendant efforts at finding their footings in the unstable climate of economic downturn leading to the formation of diverse complex identity in our social environments. Consequently, this review section held constant the appreciation of the complexities of diverse factors promoting borderlines of acquisition and non-acquisition of education but it however engages the changing educational processes in those trends explaining educational access and crime participation in the technology age. Rather than been made explicable within the etiological notion of non-acquisition of education, this trend is more appreciated within the context of human nature.

In a sporadic manner, there is a condition present at birth that accounts for the dynamism of oscillating in-between the cycle of conformism and non-conformism to societal norms. These acquired attributes are further reinforced by a gamut of other social related factors with the economic being the epicenter of dislocations. Its effect is not restricted to a particular geographical boundary, but rather global and taking the toll on the life chances of several people. With the adverse consequences of economic downturn globally therefore, the problems associated with class immobility and incremental poverty account substantially for non-predictable outcomes that are obvious in the volume of crime activism in the age of e-technologies. Economic downturn has been defined as a significant decline in economic activity spread across the economy, lasting more than a few months, normally visible in real G.D.P, real income, employment, industrial production and wholesale retail sale (National Bureau of Economic Research, 2008). Mostly affected in this economic deterioration is the youth population who are consistently groping for relevance and survival. At the helm of economic downturn is the acute closure to economic resources that are essential to the survival quest of the affected group thereby forcing them to consider crime as one of the options that are readily available to them to ward off predatory consequences of closure. Youth's involvement in crime therefore is better explained by a lack of legitimate opportunities in the social structure (Guarino-Ghezzi and Trevino, 2005; Farrington, 1996). In essence, acute unemployment despite the acquisition of credentials needed for employability instigates negative innovative tendencies that are often culminating into diverse experimentations with illicit behaviours. Once the youths are idle, the society must of a necessity brace-up to contend with probable anti-normative conducts (Millie, 2009:62). This suggestion is in line with Farrington (2007:223) disclosure that criminal behaviour does not generally appear without warning. The presumed hub of illicit activity relatively opened to potentially vulnerable youths lies with the Internet. The Internet is full of excitement and adventure, but it is also full of danger and often provides opportunities to unknown bandits (Kowaliski, Limber and Agatston, 2012:8). As a matter of fact, the threshold of crime activism snaps when the forces that bind people to society are weakened or broken.

Similarly, few other theorists equally emphasized the economic powerlessness of youths in society or community experiencing structural closure. Youthful response follows the pattern of sub-culture of "smartness" often exemplified in cunning, conning and street sense. Youths in this category are known with too little education and IQ (Cohen, 1955; Miller, 1958; McShane and Williams III, 2007). The paradigmatic position on low education as a correlate of high risk predisposable factor for participation in delinquent and criminal behaviour is popularly known in criminological theories (Fagan and Pabon, 1990). Harlow (2003) in his study found that 68% of the state prison inmates, 50% of the Federal inmates and 60% of all inmates did not obtain their regular high school degree. This trend empirically cut across the correctional structures of most nations today. Wolfgang, Thornberry and Figlio (1987) for example

attributed 70% of offenses committed in Philadelphia to those in this category. This trend is the same for Nigeria. Farrington (1989) equally linked limited education to violent crimes affecting those in the ages 16-32 and with the accumulated convictions between ages 10 and 32, thus higher than the other category. In the same vein, Sweeten, Bushway and Parternoster (2009) reported a little consensus on the relationship between deficient schooling and delinquency. In their submission, inability to acquire requisite education makes the affected person prone to anti-social behaviour. This hinges on the fact that school dropout has a causal impact on delinquency and conversely, committing delinquent acts and other problem behaviour has a causal impact on dropping out of school. This causal relationship is said to be reciprocal rather than unidirectional.

Campbell (1990:173) extends the theoretical leaning on limited education as a precursor of crime to cover female offending. In her view, female enter into crime environment as a result of addressing many problems of their lives. Problems identified include; limited educational and occupational opportunities, subordination to men, child care responsibilities and the powerlessness of underclass membership they share with males in their communities. The female has the share of acute troubles in all known recessive economy. More recently, Hagan (2013) identifies two relationships that exist between education, crime and delinquency. First, the acquisition of higher education enhances self-esteem among its beneficiaries and second, there exist an inverse relationship between the amount of formal schooling individuals possess and the arrest rate of traditional crimes. The explanant of crime or delinquency participation or non-participation can be found in the varied accessibility to educational statuses that are opened to the possessors of education within the economic structure of modern nations. There is a significant increase in the employability of acquirers of “substantial education” while those that are “deficient” appear to be vulnerable to crime involvement (Schweinhart and Weikart, 1980).

In a contradistinction from what several literatures have reported on correlation between inability to meet up educationally and involvement in crime (MacDonald, 2007; Beinart, Anderson, Lee and Utting, 2002; Flood-Page et al, 2000; Capsi et al, 1998; Graham and Bowling, 1995), recent development clearly shows that increment in education does not necessarily curtail participation in delinquent or criminal behavior. It is a known fact that criminologists and educators have long speculated that increasing the educational achievement of young males might lower the probability that they engage in criminal activities (Moretti, 2005), findings from this current study espouses the fact that acquisition of more education is a pre-requisite to becoming successful in crime in the modern electronic environment. This research finding is supported by earlier findings (Denno, 1985; Day, Franklyn and Marshall, 1998). Majorly implicated in this criterion involves the sophistication involved in cyber technology permissible crimes. Germane to current study therefore is the necessity of acquiring education on the basis of operationality of cyber technology (most especially the Internet) which is a pre-requisite for achieving breakthrough in cyber fraud.

Method

This survey that was conducted in Lagos to unravel the causes of youth's participation in cyber fraud adopted mixed method design for data gathering. The quantitative approach identified two categories of respondents while the qualitative content was supplied through Focus Group Discussion and In-depth Interview. The latter was used to reinforce the quantitative data. The first category consists of youths residing in the general public of the study area who were assumed to be non-participants in cyber fraud activism. 1000 copies of the questionnaire “A” was administered to this group. The second category were youths suspected to be perpetrators of online fraud and was purposively accessed in diverse cyber cafés

in the selected area. 800 copies of questionnaire “B” were allotted and administered to this group. For the purpose of sampling, Lagos state was delimited into three senatorial districts forming the entirety of the state (West, East and Central districts). In line with the number of Local Government Areas in the state, (twenty in all), six Local Government Areas were used for the study. The West having ten Local Government Areas by virtue of its size was allotted four while East and Central having five each produced one each for the study. The Local Government Areas so selected were randomly selected adopting the principle of sampling without replacement. Reporting on the retrieval rate, a total of 805 copies was recovered and analyzed for those in the general public while a total of 426 were retrieved from the suspected category and processed. At the level of analysis, two hypotheses that were instrumental to knowing the role of education in online fraud activism were tested. The two featured three important variables that helped in the research effort toward ascertaining the causal factor of fraud participation on one hand and determining the level of education needed to be successful in cyber fraud business on the other hand. In relation to the qualitative methods adopted, focus group discussion (FGD) and in-depth interview (IDI) sessions were conducted. A session of FGD was conducted in Ikoyi prison in Lagos with seven participants who were mainly fraud convicts. IDI sessions comprise the engagement of two fraud convicts who disclosed their knowledge and participation in online fraud prior to their incarceration, two participants from the youths in the general public of the study and two representatives of the Economic Crime and Financial Commission (EFCC) staff accessed in Lagos and Abuja. Inputs from these respondents were analyzed in the data and analytical sections of this paper.

ANALYSIS OF PRECIPITATOR OF ONLINE FRAUD

In a bid to unravel the instigators of cyber fraud with the view of knowing the explicable factor in education-crime nexus, the respondents were asked to give their opinions on the probable factors promoting cyber fraud. The responses provided by the surveyed population are depicted in the figure.

As depicted in Figure 1, 12.6% of GPY and 10.0% of YSC disclosed that the existence of corruption in Nigeria accounts for the spate of online fraud while 11.6% of GPY and 8.1% of the YSC blamed bad economic situation on the prevalence of cyber fraud. Similarly, 3.3% of GPY and 2.8% YSC viewed parental neglect of children in modern society as the probable cause of crime among the youths. Peer

Figure 1. Respondents views on the causative factors of cyber fraud in percentage

GPY: General public youths

YSC: Youth in the suspected category

influence was given as the instigator of fraud by 3.1% of GPY and 4.9% of YSC while 0.6% of GPY and 3.7% of YSC lamented that the inability of youths to secure admission into colleges to pursue higher education explains their involvement in fraud. Youth's unemployment secured a relatively large response from the two categories of respondents. 37.2% of the GPY and 39.0% of the YSC directed attention to the problem of unemployment in Nigeria as a major cause of youths –crime participation. Unemployment in this regard polled higher when compared to other factors fingered by the respondents as a probable cause of cyber-fraud. In the same vein, 1.4% of GPY and 5.6% of YSC attributed frustration attendant to survival instinct as the push factor in youth's crime participation while the high rate of poverty was seen as a vital preponderance of youth's involvement in crime by 12.9% of the GPY and 6.5% of the YSC. Finally, 8.4% of GPY and 4.6% of YSC mentioned other causes such as the defective nature of the configuration of the Internet technology, which often gives room to illegal manipulation, some viewed it as criminal conduct while few other dismissed it as youthful fun.

Summarily looking at the data, it is very clear that the amalgam of attributable factors identified by the respondents' count when situating the probable causes of cyber fraud. Yet however convincing these arguments may be, decorum demands that one should limit his/her search to at least a researchable factor. It then became compelling to zero on the effect of unemployment on youth-crime participation just as appreciable number of respondents opined that it accounts for the current situation. Apart from opinion expressed by this latter category of respondents, one should rarely draw inspiration from the old maxim which states that "idleness is the progenitor of negative inventions", hence the need to restrict the research attention to the occurrences within the borderlines of unemployment in Nigeria. As a fundamental social problem in the modern world, unemployment often pressures or impresses it upon the unemployed to engage intellectual reflection towards survival in the face of daunting circumstances. The consequences of these decisions that are attendant of pressure posed by joblessness on both learned, unlearned and other set of people which affect the ordered state of relationship in the virtual environment informs the conduct of this study. As a matter of fact, unemployment by its nature promotes a remarkable linkage between youth quest for survival, relevance and crime participation. Consequently, further effort was made to determine consequences of unemployment for increment in cyber fraud. This is done by testing the relationship between unemployment and crime.

Unemployment and Crime

Unemployment has severally been blamed on the rising rate of different types of crime in all known society. In 2009, ILO report shows that in the year 2008, with an estimated 190 million people world-wide—6 percent of the global labour force was revealed to be unemployed. Similarly, U.N.O. (2005) also espoused that globally, youths without jobs create a risk for crime, violence and political conflict. It is in view of the enormity of jobless people and its attendant risk located in crime involvement that an attempt was made to examine the contribution of unemployment to the ongoing youth's negative cyber culture. Theoretically, youths without jobs are completely fenced out from the mainstream societal goal attainment thereby suffering non-inclusion. The unemployed often experience the non-realization or dislocation of aspirational needs and are confronted with the risks of survival. This is valid from the standpoint of R. K. Merton's perspective. Therefore, in an effort at testing a relationship between the two variables of unemployment and crime, a cross tabulation was done. The examination was meant to know if unemployment among the youths has significant impact on the prevalence rate of cyber fraud on

one hand and to know if it has any effect on the decision of more educated persons to engage in crime on the other hand. To give a robust finding, the significance and the strength of relationship that exist between both was investigated through the use of chi square and phi correlation coefficient.

The cross tabulation in Table 1. Indicates that in testing the relationship between unemployment and cyber fraud involvement, 404 (100%) respondents of the YSC gave their responses, however, it was only 23.0% who agreed that there exists a correlation between unemployment and cyber fraud participation among Nigeria's youths. The Chi-Square value indicated 1.243 at p-value of 0.265 which shows a statistically significant relationship between the two variables compared.

The phi correlation coefficient was used to increase the depth of our understanding of the relationship that exists between unemployment and cyber fraud involvement. The result at a value of -0.55 shows that there is a relationship between unemployment and cyber fraud participation among the youths. In relation to the strength of association, it is very weak. This result is not quite unusual since earlier research had shown that the relationship between unemployment and crime remained unsettled and aggregate crime rates and aggregate unemployment rates seem weakly related across diverse studies in most cases. Once a youth is wrongly positioned by reason of joblessness, its attendant impact may be devastating. Association was earlier observed between family poverty (often sustained by unemployment), youth motivation, achievement and behavioral dislocation (Brook-Gunn and Duncan, 2007). Research has equally reported that those who suffer as a result of unemployment stand the risk of having no income and at the same time encountering various other difficulties (Furaker, 2009; Strandh, 2000; Alm, 2001). The existence of lack of opportunity instantiate higher crime rates and crime becomes more acute when youths have to jostle for the limited number of spaces in the job market for placement (Siegel, 2010).

Research has established a relationship between unemployment, poverty and invariably crime (D'Alessio and Stolzenberg, 2002:178; Pastrana, 2009). The economic model predicts that as opportunities—jobs—become scarce, the relative attraction of illegal activities is enhanced. And as more and more youths face stiff challenges, the tendency to source for the alternative becomes rife. It is quite obvious as few scholars have alluded to this. Rosenthal (2005) argues that "Financial pressure contributes to the incentives to create fraud. High rates of unemployment among the youths has been accentuated by research (NISER, 2007). Unemployment is a purely socio-economic problem. Rather than been construed as individual's faulty character (Especially when youths are accounted as indolents) or lack of job skills, unemployment is a public issue that results from the failure of the economic and political institutions of

Table 1. Chi-square test illustrating relationship between unemployment and cyber fraud involvement

Unemployment among Youths	Trying to get money/property		Total
	Yes	No	
Agree	85 (23.0%)	284 (77.0%)	369 (100%)

society to provide job opportunities to all citizens (Mooney et al, 2009). Youths are the most affected when considering the challenges of unemployment and with grave implications for socio-economic relationships (Edwards, 2009). With the downturn in the economy, the perception that the opportunity to commit fraud is there for taking, coupled with financial pressures, provide the incentive for rising level of on-line fraud and other types of crimes. The prevalence of crime among Nigeria youths draws strength from the situation of unemployment. With the existence of unemployment therefore, all road then leads to the experimentation with diverse probable alleviators in which the use of ingenuity and the application of intellectual abilities represents but one of other solvents. In this regard, the adaptation of gained educational knowledge is instantiated by the pressure posed by unemployment. Education resource in essence, creates the easy landing into the manipulation of instrumentation of fraud which is knitted with modern Internet technology. Educational knowledge assists in the youth's quest towards navigation or surfing online to access and curry to themselves electronic borne "smart" money alongside other choice goods. In an attempt at situating the processes in a clearer perspective, further examination is made to control for the relationship between education and crime.

Education and Crime Affinity

To zero in on the relationship between education and crime participation, effort was geared towards knowing the depth of relationship by testing the level of significance through the use of chi square. The phi correlation coefficient was also used to determine the strength of the relationship. Finally, the crammer's value was generated to indicate the strength of association.

The cross tabulation in Table 2. shows that in the relationship between education and cyber fraud involvement. 412 (100%) of the YSC responded to both items. 5.2% of the respondent obtained primary school leaving certificate, 28.9% were school certificate holders, 20.0% had OND/NCE certificates, 41.0% possess HND/B.Sc. degrees and 3.0% other were either professionals or would have obtained one skill or the other with or without official reckoning. This may likely include people with no formal education (popularly called illiterates). The Chi-Square value indicated 17.55 at p-value of 0.002 indicating a sta-

Table 2. Chi-square test illustrating relationship between education and cyber fraud involvement

Education	Trying to get money/property		Total
	Yes	No	
Primary	5 (38.5%)	8 (61.5%)	13 (100%)
Secondary	28 (15.6%)	152 (84.4%)	180 (100%)
OND/NCE	20(25.3%)	59 (74.7%)	79 (100%)
HND/B.Sc	41 (34.7%)	77 (65.3%)	118 (100%)

	Cramer's V	.206	.002

tistically significant relationship between the two variables compared. Examining this from the context of existing literature, research finding have earlier established a reciprocal relationship between the risk factor inherent in educational deficiency and the outgrowth of criminal instinct in youths cross culturally (Kraemer et al, 2001). However, this study obtained a different result. It was obtained that educational attainment forms a pre-requisite to being able to function and remained successful in cyber fraud business. This is a departure from the conventional sense explaining the preconditions to becoming criminal.

The phi correlation coefficient was deployed to test the strength of the association between the two variables. The result at a value of 0.206 showed that there is a significant relationship between education and fraud involvement. The relationship is however weak.

Crammers view intensifies our understanding of the depth of the association between education and cyber fraud involvement. The result at a value of 0.206 still reflects some degree of association between the two variables but also at a weak level. In evaluating the type of relationship that exists between education and cyber fraud involvement, it was noticed that a significant relationship exist but not strong enough to explain the reason for the current trend in youth's crime participation. Further examination was made through the use of qualitative methods to generate the potency of such relationship. This additional data gave credence to the essentiality of educational acquisition in defrauding others in the modern day online relationship.

In the data presented in Table 3, 43.9% of YSC directed attention to the immense value that educational acquisition confers on becoming an expert in cyber fraud arena. This in a way may be uncontestable when one looks at the dexterity needed to con others that are of equal intelligence as the fraudsters or better still even if not superior in knowledge to those to be conned. Research data also confirmed the additional advantages that higher educational qualifications provide to con artists in their quest to access higher and fertile opportunities in the e-business environment. 49.9% of YSC reiterated the benefits derivable in the possession of higher school certificates especially as it helps in the manipulation of sophisticated softwares that are valuable in accessing more lucrative targets such as that of institutions, industrial and governmental organizations. However, looking at this relationship from the qualitative base, there is an affinity in part and there also exists some dissension. Although, three respondents that participated in the FGD had earlier expressed skepticism about the necessity of education in the perpetration of fraud but the two other respondents with vast knowledge in on-line fraud were of the conviction that education is important to being successful in cyber fraud business. However, while the expression of skepticism came pungently in the submission of the former, it was a different case with the self-confession with another two interviewee drawn from the convicted fraudsters (though this two were not exactly convicted for cyber fraud but both have previously perpetrated cyber fraud) engaged in Ikoyi prison. Those who viewed education as unimportant to fraud success have this to say:

Respondent A. Sir, fraud may not require too much education. But I may not know if cyber fraud requires education to be successful.

Table 3. Educational factor in cyber fraud involvement (quantitative input)

Variables	Percent
	n=426
Education is important to being successful in yahoo fraud	Yes
Attainment of Higher education will confer more benefit to fraudsters.	43.9
	49.9

Respondent B. 419 people are guy man. They are not like you who have certificates. What is necessary is the right tip and you follow it up?

Respondent D. I don't know much about yahoo but I do know that education is not compulsory to operate property fraud. You needed only to be sharp, get right information on offers and be calculative.

Considering the positions of these three respondents, it is very clear that they both belonged to the category of the traditional fraudsters. The fraud professionals in this category rely to a large extent on calculative intelligence which may or may not require the application of complex technicalities demanded by the new technologically driven fraud. In the traditional context of fraud, educational acquisition is not a prerequisite. Both 'common' and 'uncommon' sense guarantee success.

But contrary to the reactions expressed above in the course of FGD exercise on the non-importance of education to being successful in online fraud, two respondents who were thought knowledgeable in the art of online fraud (drawn from the FGD respondents) were later selected for IDI and their views are recorded below:

Respondent C. In cyber fraud, you need to know how to key into the psychic of those 'mugu' (fraud victims). Operation of the Internet requires the right word and the manipulation of the right softwares. If you are not educated, how do you use 'bulk sender' software to reach out to as many people in the cyber space? How do you load your cards with the appropriate sum of money that suit your purpose? How do you know how to respond and counter all obstacles that won't allow your victims to deliver? Let me tell you, without being educated you cannot get much from yahoo. I have been into this for some times now. I am talking from experience though, yahoo crime is not what brought me to prison. It is the collection of money from people under the pretext of securing international passport for them that caused my being docked. To be truthful, I always engage the faking of such document on-line.

Respondent F. 'Yahoo boys' are in their various classes. Don't venture into yahoo if you are not adequately educated. All what you needed to operate successfully require technical knowledge on how to get across to people who will flow along with you. There are diverse area of interest you must take care of. Most importantly is your ability to conceal all the leads that can expose you to arrest and prosecution. How do you do this without having adequate knowledge in manipulating the Internet? Concealing your identity and country of operation is quite important. You may be operating in Nigeria and can as well disguise as if you are in London. There are softwares that can make you a clean impostor. What about accessing other people's bank account in various international banks? All of these requires the ability to be adequately educated. Sir, for instance, how do you trail government cheques moving from one destination to the other if you cannot manipulate a tracking software?

Analyzing the submissions of this operators or professionals in online fraud, it is glaring that robust success can only be attainable when one gets extensive education that will help any would-be criminal manipulate diverse software that make online crime robust. The immense value of education to cyber-crime cum fraud maturation cannot be underplayed. This is obvious from the reasons jointly alluded to in relation to the importance of education to cyber fraud as expressed by those who have operated this type of fraud in the past. This finding represents a point of departure from the known paradigm of what

guarantees being successful in the traditional fraud crime in particular and in most crimes in general. Several researches as often dismissed criminals or youths into crime as school drop-outs but the reverse is the case with on-line fraud for instance and for other virtual driven crime unfolding in the modern society hence the need to have a theoretical rethink on the relationship between education and crime in the criminological circle.

CONCLUSION AND RECOMMENDATIONS

It is a pre-requisite to any criminological endeavor to capture why people engage in crime activities, determine factors enhancing their choice of criminal mode and spontaneously generate a robust principle and other forms of knowledge regarding the handling of deviance and anti-social issues. This trio constitute the subject matter of this paper given the ontological status of virtual crimes. Ideally, this study captures events unraveling in the ICT arena which is unabatedly featuring a staggering number of cases of cyber related victimization basically leading into loss of resources and simultaneously heightening the status of fear in the use of e-technologies. Importantly, this paper systematically queried the veracity of the hitherto postulation regarding the inverse relationship linking crime participation and educational attainment. It was noted that the complexities attendant of the modern e-relationships that are consistently enabled by virtual technologies requires a concerted re-examination in criminology theoretical field. It is informative to know that, just as the nature and operation of crimes are changing, so also is the reduction in the capacities of existing criminological theories in comprehending its ramifications. In the cyber environment, apart from the fact that there are diverse emerging crimes that may be dismissed as “non-utilitarian” when assessed from their end results, it is glad to state emphatically that they confer satisfaction on their perpetrators and inflict injuries on diverse victims globally. Crimes such as cyber stalking, cyber bullying, cyber rape, and host other crime in the virtual environment may fall into this category. Asides from cybercrimes that were for the purpose of convenience classified as non-utilitarian in the true sense of it, there are other cyber related crime requiring unique intelligence and special intellectual capacity to operate. One may be delighted to know that those in this category command high rate of return in gains or benefits to the perpetrators. Crimes in this category is well grounded and best examined from the purview of the quantity of education at the disposal of virtual crime inducers at any given moment. This study firmly asserts that education in the modern e-environment is unavoidably important in getting economic goods in both legal and illegal activities. It permits the penetration into the realm of the unknown, confers deeper understanding of criminal tactics in reaching out to a vast majority of ICT users and thus increase their levels of victimization. This category of crime equally broadens the latitude of criminal operation into all sectors of criminal interest. This is made possible by reason of mass adoption of ICT technologies to meet domestic requirement of a myriad of people all over the world. This arena remains a platform for manifold opportunities with its flexibility in creating a convergence for both morally upright and depraved persons to operate with little or no restriction as to what their intentions may be. However, ICT environment made available its operation in unequal terms since the medium imbues those with higher educational qualification the capabilities to think haywire and to expand the web of vulnerability for other users. It is on this basis that an inward re-examination of the current theoretical assumption on “little education” higher involvement in crime and “higher

education”, minimal cases of crime participation is recommended. This option becomes expedient as more and more human interactions tend to gain their bookings in the virtual world. With this change in focus, it will equip the enforcement agencies the skill of beaming their search lights on those hitherto construed as non-infectable, or insulated in crime epidemiology. The hub of crime in the virtual era is linkable to the activities of those classified as enlightened, educated and calculative, hence there is a need for theoretical renewal and recalibration. This effort if expeditiously engaged, will aid speedy crime tracking system, usher in improvement in online related crime appreciation and increase the rate and certainty of arresting cyber implicated crimes globally.

Development of Crime Sociology From Bureaucratic Iron Cage to Digital Determination

1

Muhammet Ali Köroğlu

Uşak University, Turkey

INTRODUCTION

As a necessity of being a social being, humans have lived as groups and in communities throughout their entire history. The collective life has required some values, norms, and rules. As normative qualifications for human behavior values, norms, and rules are based on social order and the continuity of social life. For a very long period of time, social institutions, such as religion, morality, and politics were determinants on the individual and social behavior of human beings. Legal systems were then created and the provision of the behaviors was determined in detail. It can be said that legal systems are based on the negative behaviors of people, namely their criminal behaviors. However, there have always been individuals who violate the rules and legal norms required by social life. In its most general form, behaviors that violate the rules can be expressed by the concept of crime. Although the legal response of any behavior varies according to societies, crime is a sociological phenomenon that exists in all societies. Thus, Emile Durkheim, who describes “crime” as an action deviating from social rules, also defines a certain amount of crime as “normal.” After the first sociology classics, all the theories that emerged in the study of crime can be evaluated in different categories, such as sociological, psychological, and biological (physical, mental character). All these theoretical approaches explain some aspects of reality related to classical criminal behavior. However, new approaches are needed to explain the crimes committed in today’s virtual world.

With the previous revolution of human civilization, people have experienced the freedom of time, space, and labor. This situation was criticized by Max Weber (2000) as being a bureaucratic iron cage. In the last 50 years of human civilization, most people who became acquainted with the Internet considered it a freedom, transparency, and participation in the process of knowledge creation. However, it was understood that the world of the Internet could be an area in which all of the criminal acts known in classical literature could be realized. Moreover, by getting rid of all the restrictive norms that exist in the social world, a field of discharge has emerged in which man can act with the “id” completely in the Freudian sense.

First of all, the distinction between public and private spheres has disappeared. Thus, the Internet has become a field for socialization, anonymization, and catharsis. This has turned the Internet world into a risky area for many crimes, from property and personal crimes to crimes of terror. For this reason, the legal systems have had to further develop and create new security measures. Thus, a new social control mechanism has been developed through the security of the Internet world and its actions. It is likely that humanity would also be sentenced to the digital panoptic cage from Max Weber’s bureaucratic iron cage (Weber, 2000).

DOI: 10.4018/978-1-5225-9715-5.ch015

BACKGROUND

Crime refers to a negative value of human behavior. The act of valuing human behavior is carried out by others. Man is the only living creature capable of producing ideas about himself and his environment, questioning the value of his behavior, and seeking out the ideal. The history of humanity is the history of the effort to achieve the best for human existence. The act of crime is a phenomenon that is always present as the dialectic of this humane effort. For this reason, as a necessity of being human and being social, virtuous behavior, as anti-crime behavior, covers the whole of human history.

Throughout history, all societies have sought to determine and evaluate the behavior of their members in order to protect themselves and their social systems. For the valuation of behaviors, social institutions were produced. Social institutions, such as political systems, the legal system, religion, and family, have provided limits and legitimacy in all areas of life in which the actions of the individual can be related, and this is still the case. Human behavior may be related to the individual himself, other human beings, the social and political system he lives in, the ecological system, and, if he believes in a particular religion, his God. For all these fields, all societies produce mechanisms that set values and limits to individual behavior. The crime phenomenon emerges as a deviation from the legitimacy standards set by these mechanisms. For this reason, all societies want to control the behavior of their members and gain the behavior habits that they accept as ideal.

It is possible to find this thought even in the works of intellectual personages of the ancient age. Aristotle and Plato viewed crime as the negative extremism of human emotions and actions. Justice was considered as the balance of feelings and actions. However, there are some acts, such as theft and murder, and these acts are considered harmful and criminal. For human actions in this regard, the balance situation is not sought. According to Ross (1993, p. 239) individuals can gain virtuous behaviors through the educational institution. The phenomenon of crime, although changing from society to society, is a phenomenon that is always present and discussed. This discussion also brings about a discussion of how to control human behavior. Throughout civilized human history, an internal control had been targeted through the religious institutions. In the same way, external control was attempted through political institutions. Most of the time, the political control mechanisms supported by the religious institutions worked together. Thus, the orders of God and the king have drawn the boundaries of legality and crime together. After the understanding of science created by the age of enlightenment, science began to put limits on human behavior.

Each individual plays the roles they have defined for themselves in the social life by occupying the designated status. The only area in which an individual can act freely and in his own capacity is the private sphere. In the modern period, it for humanity's social behavior to be controlled by institutions, such as work, school, hospitals, prisons, etc., has been criticized by many social scientists. While Karl Marx (2000) criticized the process of alienation and the loss of human creativity, Max Weber (2000) envisioned the boundaries of human actions to a bureaucratic iron cage. Weber (2000) defined the rational, soulless, and emotionless social world as a world whose magic has deteriorated. In the next process, the private sphere, which is the only area where human behavior is not identified, is now invaded by millions of eyes via the Internet. The phenomenon of crime, representing the dark side of human nature, reinvents itself with new communication possibilities and technologies.

Today, with the accessibility of the Internet a reality in the lives of most individuals, the act of crime undergoes a structural transformation with the redefinition of time and space. This structural transformation also transforms the control mechanisms relating to human behavior. The virtual world offers the

possibility of crime, as well as the possibility to monitor and control human actions that are likely to commit crimes. In the context of Internet and artificial intelligence opportunities, the psychosocial processes that enable the emergence of criminal behavior should be re-evaluated. In fact, starting from the definition of the concept of crime, criminal theories should be considered in relation to the new situation.

When the literature on crime phenomenon is examined, it is seen that crime is evaluated by the fields of sociology, psychology, biology and neurology. Since these areas address different aspects of human reality, their definition of crime also changes. Therefore, new perspectives on crime should be developed by reassessing the theoretical approaches of the related fields in the context of contemporary artificial intelligence and Internet technologies.

THEORETICAL APPROACHES ON CRIME

Crime is an act that is essentially committed in violation of a law, or by not performing the behavior required by law. The law is officially applied rules by a political authority. The elites, who generally possess state or state power, define crimes as actions that violate the norms and values strongly accepted by society (Zastrow, 2013, p. 406). The concept of crime is mostly evaluated together with the concept of aberration. Aberration refers to behaving differently from behaviors considered normal and correct in a society (Zencirkiran, 2016, p. 231). The concept of aberration in everyday language means deviating from an accepted path. In this respect, it expresses the behavior that is not appropriate to the expectations and norms of a particular group. Aberration can be rewarded, punished, or accepted, without reward or punishment (Göktuna Yaylacı, 2012, p. 181). In a society, no one completely violates the rules, and no one completely obeys the rules. In some cases, most people break some generally accepted codes of conduct (Giddens, 2000, pp. 182-183). However, each violation of the rules may not reveal the category of crime and punishment.

The Sociology Dictionary links the concept of crime with law and authority. “Crime, according to Marshall’s (1999, p. 702) definition is, “An action that exceeds the personal sphere, including the boundaries of public sphere, and violates the rules and laws that are prohibited, requiring intervention of penalties or sanctions or a public authority (state or local institution).” According to this definition made from a sociological perspective, the actions outside the borders of the legal order are considered crimes. Aberration is a concept close to crime, but refers to actions that do not include the evaluation of the judicial system. Aberrant behavior is punished by social control mechanisms, such as values and norms, until it reaches the legal system. Considering whether a behavior is applied sanction by the legal system or society, it is possible to decide which category will be evaluated as a crime or as an aberration (Dolu, 2013, p. 3). Accordingly, the legal system punishes criminal behavior and the social system punishes the behavior of aberration.

Whether they are legal crimes or social aberrations, undesirable behaviors that are subject to social and institutional intervention continue to exist in all societies. The oldest types of crimes in the memory of humanity, such as murder, theft, and sexual assault, have evolved into new forms by evolving in modern society. While deviant behavior in the human fiction of modernity was defined as irrational behavior requiring reformation, the technological possibilities provided by the Internet also provided new forms and avenues for criminals. Criminal behavior, which is a multidimensional subject, is widely evaluated in terms of predicting human behavior, changing and controlling human behavior, political power, and

physical health standards. Therefore, theories about crime and deviant behavior are developed by sociology, psychology and medical disciplines in the context of the human imagination of modernity. It is possible to talk about many theories, but it is important that these theories are re-interpreted in relationship to the Internet and artificial intelligence (AI). First of all, it is important to determine the place of crime and aberration in modern society's understanding of humanity and civilization.

Modern Society and Crime

In the world of social sciences there is a significant amount of literature on modernity. As a result of a significant effort, modernity is determined by scientific, cultural, political, and industrial revolutions (Jeanniere, 1993, p. 97). It is stated that concepts, such as progress, evolution, freedom, democracy, and equality, which are the basic ideas of modernity, are possible through the liberation of the human mind (Paz, 1993, p. 185). Basically, in these principles based on the idea of enlightenment, freedom is designed as a function of the mind. According to this, man can understand and re-establish the reality of humanity and society through the mind and science. The truth about man and society is universal because the human mind and science are universal. Therefore, it is essential to rebuild life according to the universal reasoning and scientific criteria (Şaylan, 1999, p. 134). Thus, human design, as a universal unitary subject, thinking and acting with a universal mind and science, is revealed. People with common behaviors who are away from tradition, superstitious beliefs, and sensuality, acting with the same mind all over the world are foreseen. The natural consequence of this can be a period of humanity in which crime, aberration, war, and destruction become history; the common man transformed into a superior man. However, today's realities do not coincide with society's expectations. Crime, aberration, and humane disasters have become more and more sophisticated in today's world than they were throughout all periods of history, and this is due to the availability of new technologies that have opened up more ways for people to communicate and socially interact, such as through social media channels on the Internet.

It is possible to see one of the most effective criticisms of determination and identification of human behavior in Weber's (2000) research. His concept of bureaucracy refers to the hierarchy and behavior patterns defined within the framework of rational action logic. Once a bureaucracy has been established, it does not mean that only one work is most rational and profitable. It becomes a social structure that cannot be eliminated. Bureaucracy becomes a means of transforming collective action into social action, which gains rational regularity. As a means for socializing power relations, a bureaucracy becomes the most important instrument of power for those who control this apparatus (Weber, 2000, p. 311).

Bureaucrats cannot control the system because they become part of it; they cannot prevent its functioning and cannot move flexibly. All this can be possible through the power at the top of the hierarchy. Here, then is a case of determining of human behavior in the finest detail. As a result, modern man is obliged to the boundaries of the iron cage of the bureaucracy supported by other social institutions such as education. Despite these limits, crime, corporate crimes, murder, and sexual offenses, remain in existence by changing form. The determination of human behavior totally by the owners of property is criticized by Karl Marx (2000, p. 27) as the alienation of man from himself, his nature, and his labor. In this critique, criminal behavior arises in the context of contradictions in the relations of production and property. Sociologists from the Marxist tradition regard crime as a consequence of capitalist class relations. According to them, all crimes, such as organized crime, murder, and theft, are determined by structural factors.

The human and order design of modernity, and the control mechanisms created accordingly, are criticized by many social scientists including Michael Foucault (2015) and Zygmunt Bauman (1997). Foucault, in his books titled, “Madness and Civilization” and the “The Birth of Biopolitics,” extensively describes how the modern period condemns the differences and confines the person (Foucault, 2015, pp. 7-715).

In the same way, Bauman (1997, pp. 30-32) attempts to understand modernity by the metaphor of a garden design. In this design, uncontrollable behavior is an unacceptable crime. In modernity, man has to be predictable, supervised, and controlled. Throughout human history there has never been full equality between the crime and the control mechanism. For the first time, through modernity, it is seen that surveillance and controlling mechanisms are ineffective against crime. Nevertheless, all known crimes exist by making use of the same technologies and control opportunities.

Emile Durkheim (1992, 2006), one of the first sociologists of modernity, describes crime as pathology. This is a biological concept. Crime and aberration is a social phenomenon considered normal in the sociology of Durkheim. While examining the crime, Durkheim examines the concept of punishment as a requirement of his sociological method. Crime is the act that leads to a special reaction called punishment against the offender. While there are some universal offenses, such as murder and theft, these crimes are few. However, in all societies there are many criminal behaviors that require punishment. This is about the essence of the concept of crime. According to Durkheim, the essence of the concept of crime represents a rebellion against social conscience. Society imposes the punishments necessary to maintain its integrity. The types of penalties vary according to the types of solidarity of societies. As crime and aberration are directly committed against the collective soul in mechanically solidarity societies, a punisher law is essential. On the other hand, because of the division of labor in organic solidarity societies, punishment is determined by the principle of restorative law (Durkheim, 2006, pp. 99-216).

Additionally, Durkheim states that social control is lost and anomalies occur during periods when social rules are obscured (Durkheim, 1992, pp. 245-264). Anomy, or social instability, refers to the situation in which social norms lose the power to regulate and discipline human actions. In such a situation where norms are absent or contradictory, the individual loses the measure of their behaviors. Thus, anomy becomes the cause of behaviors deviating from norms (Dönmezer, 1999, p. 236). This is due to rapid social changes. Individual norms do not work. The individual cannot know new norms. So, there are aberrations at the social level. The modern period foresees a social structure that raises risks and dangers against the sense of security, which is one of the most basic needs of man. The working principle that destroys creativity, threats that cause fear, such as the threat of nuclear war or totalitarianism, are not as not real to modern human beings, as it was to segments of humanity in past periods (Giddens, 1998, p. 16-19).

Modern human behavior takes place in the social world of such a tension, and a crime is formed. The most satisfying approach to the nature of criminal behavior has to be sociological because the nature of the crime depends on social relations and social institutions. Sociology emphasizes the reciprocal connections between adaptation and aberration in different social contexts about the phenomenon of crime (Giddens, 2000, p. 186). The theoretical approaches in the sociological context, such as labeling, learning, differential unity, and anomie, address the context of relationships, acceptances, incentives, and limitations in which human behavior emerges. Human attitudes, emotions, thoughts, and actions are shaped according to the values of his or her society and human understanding. No human being is absolutely well programmed and does not have to behave well. Likewise, no human being is absolutely bad

and is not programmed to commit a crime. Man, as the founder of civilization and the bearer of virtues, is also, as Thomas Hobbes (2019) predicted, selfish, egoistical, manipulative, and a merciless creature in pursuit of power. What determines this difference according to sociology is the social environment in which the individual develops.

Digital Identity and the Modern Actor

Identity, as a sociological concept, is the name of a process that occurs within the framework of the individual's relationship to society. In one aspect, it ties the individual to the society in which he or she lives and differentiates him/her from others. The individual's attitude towards social expectations constitutes his/her identity. The individual becomes a member of society through the process of acquiring an identity, interprets social expectations according to his/her own ideas and values. Thus, the individual's interaction with his or her society acts as an identity formation process, and this process lasts for a lifetime. Each individual creates common behaviors, values, expectations, and norms, as well as differences.

The concept of identity in the modern era is formed within the framework of the concepts of public sphere, state, citizenship, and autonomous actor. The relationship between the individual and the state is established by citizenship laws, and a sense of belonging is created (Marshall & Bottomore, 2000, pp. 36-50). The public sphere emerges as a discursive field where the individual, as a rational actor, expresses his/her own demands and expectations. The real determinant of identity is the public sphere, because identity is manifested as a concept shaped by modernity. The identity is given to the actor and it becomes a part of the public sphere. The fact that the actor can participate in the public sphere without being declared guilty or banned obliged to acceptance of this identity which is presented by modernity. This identity, defined by modernity, depends on acting as someone with the principles of universal rationality. Thus, reason, law, science, morality, and the actor, become universal with this principles. As a result, the modern public sphere pushes the specificities, localness, and differences of the actor, whom it considers irrationally, into a private sphere. The public sphere turns into the field of cultural and political power of modernity (Karadağ, 2006, p. 55).

In today's modern era, the sociological context of the concept of crime develops on the basis of individuals and groups excluded from the public sphere. When the groups excluded from the public sphere are examined closely, ethnic groups, religious groups, women, ghetto inhabitants, and people living in poverty, come to the fore. Ethnic, religious, and cultural exclusion forms the basis of terror, drug trafficking, human trafficking, murder, ransom, and all kinds of political crime. Poverty and demographic intensity in the ghettos provide a broad culture of crime, ranging from theft to sexual crimes. On the other hand, the criminal behavior of individuals and groups who express themselves in the public sphere is more qualified and more sophisticated. Corporate crimes, tax evasion, money laundering, and crimes against human dignity are committed according to the rules of the universal system. Then, with the development and socialization of mass media, the concept of a homogeneous public sphere changes in structure and function. Mass media becomes an economic value and begins to determine public opinion according to private interests (Habermas, 1997, pp. 309-328). The elements belonging to the whole private sphere and different identities begin to involve into the public sphere, which is the special design of modernity. The public sphere is attacked by the private sphere, and the distinction between the public and the private spheres is almost lost. While mass media is accelerating this process, the Internet is the largest transforming power.

The Internet is a universal public sphere that connects the whole world, and it is very difficult to control (Bacık, 2005, p. 15). The internet allows all identity groups to be present in the public sphere. Due to the Internet, the expectations of the actors who have been established in the modern world, transform. At the same time, the nature of the actors and the crimes transform. Crime is committed not by the identities included from the marginal neighborhoods or excluded from public spheres, but by actors having higher social status and advanced education. The crime becomes independent of time and space, and moves up the social ladder (e.g. white collar crimes). Certainly, traditional crimes such as murder, extortion, and theft remain the same, however, major crimes are being committed through Internet opportunities. Traditional crimes that can be committed using the Internet include crimes such as threats, blackmail, attacks on bank accounts and credit cards, seizure of digital objects, sexual offenses, pornography, terrorist offenses, terrorist propaganda, and infiltration into security systems can be more easily committed than by using traditional criminal methods.

The world of virtual relations supplied by the Internet provides a space in which individuals communicate with their social identities outside the limits of all social norms and values. The person communicating through the Internet may disclose his/her gender, age, ethnic characteristics, and social status as unlike his/her true characteristics and life. Anyone can become a personality that he/she wants to be, or wants to see, but never feels comfortable being in the real social world. This is the process of disidentification by contrast, with the identities attributed to the individual through the modernity.

It is impossible to predict the dimensions of the disidentification process. An individual can watch a child rape with great pleasure in the confines of his room via the dark Internet world on a nightly live broadcast, and the next day, that same individual can talk at a conference on children's rights, as a requirement of his esteemed status. The structural personality theory proposed by Sigmund Freud (as cited in Ceyhan, 2013) might be illustrative in explaining the infinity of crimes related to identification and disidentification.

Freud believed that unconscious forces and internal conflicts played a decisive role in determining the individual personality. According to Freud, the personality structure consists of three structures: id, ego and super ego. These structures are supported by the libido, as the psychic energy. These structures form at different stages of an individual's development and are in mutual interaction (as cited in Ceyhan, 2013, p. 94). One of the most fundamental components of the personality structure, id, is genetic spiritual energy. The id includes biological, instinctive behavior patterns such as eating, drinking, sexuality, and aggression. The id acts in the sense of pleasure and satisfaction for instincts. The id's effort of satisfaction does not accept time, space, or social boundaries (as cited in Ceyhan, 2013, p. 94). The id constitutes the most primitive dimension of the human self and does not accept any excuse for the pleasures that it demands. In contrast, the ego is the center of the human personality and acts with the principle of realism. Through contact with the real world, the ego controls consciousness. It determines rationally how to be satisfied in the real world by controlling the demands of the self. The super ego is the moral and social aspect of the human self (as cited in Ceyhan, 2013, p. 94). While the ego forms the rational dimension of the human self, the super ego forms the moral and social aspects of the self. Criminal activity derives from the deterioration of balance between these personality elements. For a balanced personality, a demand requested by the id, is judged through the ego, and met, if it is suitable to the super ego. However, if this balance deteriorates, the demands of the individual's primitive aspects try to become satisfied in the social world. Thus, crimes come into existence in the real world.

The process of disidentification in the Internet world also functions with the same mechanism. All demands from the id are transferred to the virtual world uncensored. For the most primitive demands that can never be imagined in the social world, the virtual world becomes a field of discharge. There is no mechanism to run the super ego. The ego confuses reality and virtuality, thus, primitiveness and savagery can find a place in the virtual world more easily than ever before in human history.

The id, as the primitive component of the human self, cannot be limited and it is not possible to limit the crimes committed in the Internet world, especially on the dark Internet. Rather than a traditional armed bank robbery, it is very comfortable to rob a bank in London by sitting in a remote town in Asia and transferring money from one account to ten accounts. Moreover, national boundaries and legal systems do not apply to the digital world. The largest value of this unlimited world, established with Internet networks, is data. Those who control the data, also control the lives of others. All kinds of digital operations, GPS devices, mobile phones, computers, credit card transactions; basically, all actions in daily life, leave a lot of data behind them. It is possible for malicious people to control the life of an ordinary person by accessing and using the person's personal data.

Thus, the virtual world turns into an area where many offenses can be committed very easily, such as sexual harassment, identity, data and bank theft, child abuse and pornography, murder and drug transfer, blackmail over photos that could discredit individuals. Moreover, centralized control over the Internet is impossible, because the Internet is a shared area. It does not have one owner. It is also technically very difficult and costly. For this reason, it is not possible for national auditing and international agencies to follow-up on crimes committed via the Internet (Taşkın, 2008, p. 16). The crimes of the former world are becoming a part of more people's lives today due to the new technologies. The former criminal organizations intervened more categorically with human life through gigantic data (Goodman, 2016, pp. 125-141). The biggest victim of this situation was the individual. The individual is alone and vulnerable against the criminal world. Global corporations and national strategic data units spend millions of dollars developing new security measures. However, the national legal processes for the individual is handled very slowly and the individual often becomes a victim in this process. For this reason, it is possible to say that the biggest need of the digital world is the need for security, which Abraham Maslow, (1943) gives place to as the first rank, according to human necessities.

The problems here are the globalization of the interaction over the Internet, the monitoring and control of all kinds of data belonging to the users from all over the world, and the lack of defense power of the individual. When control systems, such as Promis, Echelon, etc., and global surveillance systems are added to this situation, the control over people reaches the most advanced level in history (Dolgun, 2005, pp. 186-187). With such programs, the individual can be monitored by the intelligence services in real time and in space with their voices by being analyzed by the use of artificial intelligence or by their images being monitored by any security camera. There is no place left for the individual to hide from being traced. Moreover, this can be done not only by national security services, but also by any digital tool used by the individual, by economic national and international companies, or by criminal actors. Thus, the Internet becomes a tool of power. In the virtual world, the individual can be controlled and determined by the reason of the traces left behind him/her. As a result, the individual is being promoted from Weber's (2000) bureaucratic iron cage to a transparent, digital glass cage.

FUTURE RESEARCH DIRECTIONS

1

As long as the primitive dimension of the human self exists, the crime phenomenon will continue to exist in the same way, but it will change its forms. Often, crime actors are quick to learn new technologies. If the managers of the great observer and the powers of the big data perceive threats to their security, no individual has any place to hide. But criminals who target ordinary individuals and institutions in daily life will always continue to exist and commit crimes. Smart objects will be open to the control the malicious actions of people as long as they are connected to the Internet.

In the future, the control of everyday life can be completely abolished through the use of artificial intelligence that is still in development. Artificial intelligence is an advanced tool design that modeled the human mind (Aydın, 2013, p. 13). Artificial intelligence is a project that moves towards artificial person design. It can become similar to a human being who can perceive the environment as a person, analyze large amounts of data in the Internet database it is connected to, draw conclusions, and take action depending on this analysis. As such, artificial intelligence may become the security and military personnel of the future. AI can eliminate human error. For example, a toilet, equipped with artificial intelligence, can provide information about the health status of the individual each morning by performing a urine analysis using the AI technology. There are many predictions about the humane and useful aspects of artificial intelligence.

However, artificial intelligence performing analysis and synthesis just as human beings cannot lead to good results. Through the Internet, all artificial intelligences can communicate with one another, gain autonomous characters, renew themselves, and produce norms for human beings, and then become a threat to human civilization. Today's artificial intelligence projects, however, are far from coming to this stage. From this perspective, the project of artificial intelligence is very similar to the thought of a modern, universal, rational actor designed by the science mentality and based on enlightenment. Just as the modern actor, designed as a superior man, artificial intelligence is also designed as superior to a human. A machine that can renew itself and produce thought and action can enslave humanity. In such a world, the definition of crime may vary according to the implication of superior intelligence. However, a world in the control of such advanced artificial intelligence does not seem very possible. Artificial intelligence can analyze the data in a frame determined by humans, make comparisons and make decisions (Canan & Acungil, 2018, p. 172). However, even in situations where people cannot make comparisons, they can establish emotions, values, belief connections, and produce meaning. Upon a man's look to a woman, he can write a love story and makes sense out of death and life. Human relations create social institutions. Human life is holistic. Artificial intelligence analyzes instant data and decides according to the highest probability. The highest probability in the human world may not always be the best possibility. All of these technical developments may further colonize the human life and destroy human creativity.

CONCLUSION

Crime is as old as human history. All societies have produced values, norms, and legal systems to protect their social order, carry themselves into the future, and keep their social life sustainable. They have maintained social cohesion by controlling the behaviors of community members through these systems. Likewise, they have imposed punishments for behaviors that are non-compliant with the values, the

norms, and the established legal system. Institutions, such as religion, law, and values system produced in the context of social relations, have created legitimacy and border lines for human behavior. While values for human behavior from society to society have changed, some crimes are universally accepted as crimes. Crimes, such as murder, theft, and rape, are in this category.

The essence of criminal behavior and the mechanisms by which these behaviors emerge have been discussed in detail. The sociological approaches that have emerged within the framework of these discussions have addressed crime in the context of an individual's relationship to society. Some sociological theories have claimed that crime is learned in the process of socialization; some have claimed that criminal behavior has been internalized by labeling. On the other hand, some biological and medical theories have attempted to explain crime as a genetic and anatomical dysfunction. Psychological theories have tried to explain crime through psychoanalytic and neurological processes.

Even though the phenomenon of crime does not place in the human design of the modern era, it has always existed. Crime continues to exist as a dark dimension of the human self, by changing form in the era of the Internet and artificial intelligence. It will most likely continue to exist in the future. Whatever the level of human development and civilization, the basic crimes are the same. Criminal acts such as theft, murder, rape, and harassment have only changed dimensions. There are no differences between the robbing of a bank through the Internet and the robbing of a bank by physically breaking into a bank. In terms of the definition of the crimes, both are theft. Only the act of virtual crime has become independent of time and space.

The emergence of the Internet and artificial intelligence technologies into human life creates new opportunities for people with malicious intent in terms of crime, leaving the individual more isolated and vulnerable. In this respect, today's societies are societies where social trust is very low and the risks are very high. As long as human beings exist, there will be crimes that represent human egoism and greed, as well as human error.

KEY TERMS AND DEFINITIONS

Artificial Intelligence (AI): A machine that can make decisions, produced by modeling human intelligence.

Digital Age: The period in which smart machines are determinative in social life.

Digital Cage: Refers to an opinion that every moment of the lives of individuals is under surveillance in the digital age.

Disidentification: The disappearance of an individuals' real social identifications in the digital world.

Public Sphere: The area of political and cultural discourse of the modern actor.

Social Aberration: Diversion from common social values and norms.

Sociology of Crime: A science discipline that examines the phenomenon of crime through a sociological approach in its historical process.

The Globalization of Hybrid Warfare and the Need for Plausible Deniability

Benedict E. DeDominicis

Catholic University of Korea, South Korea

INTRODUCTION

This chapter analyzes the utilization of social media as part of hybrid warfare's efforts to undermine state security through covert means that can be illegal or criminal. It begins by highlighting the postwar globalization context that encouraged indirect and covert competitive intervention by nuclear powers within the internal politics of target polities. The post-1945 nuclear environment ended the viable application of deadly force as a purposeful policy option for great powers intentionally to select in order to attain their goals regarding each other. They battle indirectly through competitive interference within the political systems of third actors in addition to targeting not only each other, but also their own national public opinion. The aim of this competitive interference is to enable their respective local political clients at the expense of the perceived local clients of the other intervening competitor. The growth of mass public participation intensified nationalist self-determination political sensitivities. It increased local opposition and raised the political costs of overt external interference. Postwar global human rights norms developed to include national self-determination for all. Covert intervention abroad became politically preferable domestically as well to avoid negative domestic political reactions to perceived imperialism. Covert intervention in all forms decreases political resistance and costs to the intervenor. This chapter highlights how the nature of social media content distribution makes propaganda and disinformation distribution very extensive at relatively very low cost. These trends and advantages furthered the stress on covert intervention and the formation of national security bureaucracies for engaging in it. Social media propaganda operations are branded as disinformation because their source is purposefully disguised. Russian state agency Internet-based covert intervention via social media in the 2016 US national elections demonstrated that the US is part of the politically globalizing world that it helped create after 1945. The policy response to these challenges is likely to include strengthening further the intelligence/counterintelligence capabilities of the national security state.

BACKGROUND

Adamson (2005) argues that due to American-led postwar economic and political globalization, the differentiation between external and internal security threats is increasingly blurred. “[N]ew security strategies of global policing [and] surveillance [...] that emerge in response to this new environment will need to be accompanied by a set of new political strategies” (p. 44). Soviet-American global competition for political influence in the nuclear setting provided the template for what is today labelled hybrid/cyber warfare including security policy responses to it. “The covert aspect of information and propaganda dissemination ... has been of exceptional importance during the Soviet-American cold war” [*sic*] (Cottam

DOI: 10.4018/978-1-5225-9715-5.ch016

& Gallucci, 1978, p. 32). This external intervention, when observed by mobilized local political actors, would more likely be seen in effect as an intolerable violation of national sovereignty. This interference would contribute to intensifying domestic polarization within the target polity. The exacerbation of the perceived threat from the other would thus appear to vindicate the intervention by their respective external patrons in the eyes of each local client. Disinformation as a component of what is frequently called “hybrid warfare” encourages mobilization to meet the perceived threat (Isikoff & Corn, 2018, p. 44). The local competitor and its external backer depict this resistance-themed disinformation against the alleged threat to national sovereignty as in essence local. The external encouragement and support for one side or the other is purposefully disguised, if not concealed (Voss, 2016, p. 40). The multiple facets of elaborate disinformation campaigns may or may not be illegal. E.g. Russian hacking and theft of more than 150,000 emails from personal or Democratic National Committee linked email addresses was illegal. The intensely competitive for-profit US news media’s utilization of these surreptitiously provided emails via Wikileaks, weakening the Hillary Clinton 2016 presidential campaign as Moscow intended, was not. The complexity of the context intentionally obscures the external intervention in the view of local political actors.

The extent to which this resistance to outside intervention within internal politics may be plausibly portrayed as essentially local was limited. Completely masking external involvement engaging many individuals is not feasible. Aside from the exploitation of new Internet media and communication infrastructure technologies, Washington and Moscow displayed this covert policy behavior historically long before 2016 (Renz, 2016, Ransom, 1977). Target polities included domestic public opinion in addition to foreign publics (Wilford, 2017). Today, so-called hybrid warfare combines national security organizational resource deployments along with exploiting Internet-based technologies to affect the target polity’s power capabilities (Cottam & Gallucci, 1978). The latter include covert psychological social media-oriented public opinion campaigns and damaging Internet-based infrastructure hacking attacks to achieve national security and foreign policy objectives.

Self-determination concomitantly has developed into a human right, although one controversially delineated (Cassese, 2005, pp. 16, 39, 63, 75, 84, 207). Foreign meddling in a targeted polity’s internal political concerns is likely to be condemned by at least some attentive constituencies in the target polity as a desecration of this national community birthright. Determining whether or not it is actually illegal and criminal prevention and punishment is enforceable depends upon the specific legal and political conditions within the target polity. Social media and the Internet in general have expedited this intervention. They have also provided greater opportunities to obfuscate the architect of this interference.

Concurrently, one’s own unofficial collaboration with foreign actors is likely to be self-servingly viewed as not being seditious. The alliance may be formal, i.e. overtly or covertly with intent to receive funds and other material support from a foreign actor. The association may be implicit, such as benefiting from foreign-subsidized social media disinformation operations which were not directly entreated by the local client, but the latter is aware of the intervention. Since the outlay of support was not in the form of a direct disbursement to the local client or other direct donation, it may be more easily categorized as inconsequential. Certain Western political figures and their constituencies view Putin’s regime in Russia as a stronghold for traditional, so-called Christian, conservative family and national values. Post-Soviet era informal collaboration by American partisan competitors with Putin’s regime is therefore less prone to be regarded as potentially treasonous. Rather, it is another alternative resource to oppose the potentially treasonous assimilationist cosmopolitanism that so-called globalist values and their transnational and local collaborator constituencies advocate. According to this conservative populist nationalist worldview, these cosmopolitans are allegedly a threat to the nation’s sovereignty and thus ultimately to the nation’s very existence.

FOCUS OF THE ARTICLE

The Globalization of Hybrid Warfare

Cassese defines globalization as the “close intertwining” between most components of national structures and of the external, international community. The latter includes “individuals, groups, associations, State-like entities, multinational corporations, trans-national organizations, multinational financial structures, media networks, etc.” [*sic*] i.e. any external actor that is not a state (2005, p. 5). In international relations, states nevertheless remain the most important legal “person” by far despite globalization (Shaw, 2014, p. 143). In the highly decentralized and primitive international legal system, states not only are the subjects of international law. They also each individually make international law through treaty agreements and customary behavior. They interpret its obligations, as well as enforce these obligations on each other (Cassese, 2005, p. 6).

Proving intent to participate intentionally in a criminal conspiracy or collusion is necessary for a felony conviction on a charge of distributing illegally obtained classified or proprietary information. “Among the great advantages cyberspace offers to criminals are anonymity and the ability to allow otherwise unassociated individuals in different parts of the world to network on a transactional basis” (United Nations Office on Drugs and Crime, 2010, pp. 203-4.) Consequently, “organizations as diverse as the ISIS and the Zeta Cartel are using cyberspace to shape opinion and elicit respect, fear and terror” (Muggah, 2015, para. 3).

Intermediaries between Julian Assange, Wikileaks’ founder, and Russian intelligence agencies providing hacked Democratic National Committee (DNC) emails facilitates legally plausible deniability regarding Assange’s intent in publishing them (Cormac & Aldrich, 2018). Gaughan claims that the 1970’s-era US Federal Election Campaign Act (FECA) is outdated; the evidence is not clear that the Trump campaign’s Russian support was illegal under FECA (2018, 104). Trump in mid-2018 enjoyed exceptionally stable and high approval survey ratings among Republican party self-identifiers at 88%, while 7% of Democrats rated his performance positively (Dunn, 2018). Among Trump partisans, treason did not occur; indeed, their rejection of the claim reflects their disdain for Trump opponents who attempt to make it an issue to weaken Trump domestically. Republican party self-identifiers disincline to share the perception of post-Soviet, anti-globalist Russian foreign policy behavior and capability as being directly threatening to the US. Benefitting politically from Russian involvement within the US polity does not establish treason. Profiting from Russian influence does not validate the effort to nullify the 2016 US presidential election outcome and the subsequent US foreign and domestic policy process outcomes that derive from it.

Aggregation and analysis of social media user data permits microtargeting to concentrate advertisements towards specific audiences to strengthen emotional antagonism regarding other groups within the state. Intensification of polarization by Russian covert state agents via the Internet in the midst of some constituencies fearing globalization extends even to current controversies such as the effect of vaccines (Broniatowski et al., 2018).

Undermining state’s power capability can comprise undermining governmental and, more deeply, regime stability by aggravating the intensity of political polarization between constituencies within the polity.

According to a top-secret NSA [US National Security Agency (BD)] report issued more than a year after the U.S. [2016 (BD)] election, the [Russian government's covertly-sponsored (BD)] Internet Research Agency conducted information warfare along several fronts. One was referred to as “govstrana”—which the NSA translated as “crap country”—and referred to attacks meant to damage a nation’s reputation and sap its citizens’ confidence. This effort involved the creation of two types of trolls (the term for online provocateurs), one focused on influencing public opinion by amassing loyal followings, and another that used teams of four or five people to churn out a mass volume of posts to overwhelm any competition from those posting contrary opinions (Miller, 2018, p. 39).

Howard, Ganesh, Liotsu, Kelly and Francois (2018) report that the IRA’s distributions reached tens of millions of users in the US between 2013 and 2018. More than thirty million users shared the IRA’s Facebook and Instagram posts amidst liking, reacting and commenting on them. The IRA’s “activities began on Twitter in 2013 but quickly evolved into a multi-platform strategy involving Facebook, Instagram, and YouTube amongst other platforms.” They note that the most far reaching IRA social media activity was not in the form of paid advertising, but rather through social media user/consumer distribution of IRA posts, i.e. organic posting (p. 3).

Increasing the intensity of public political polarization can help undermine the national mobilization capability available to state authorities to extract and direct societal resources for achieving policy goals (Cottam & Gallucci, 1978, pp. 10-22). Rising political dysfunctionality can likewise undercut the international attraction of the ideology that a specific government asserts it represents as a function of its international influence capability (Ibid.).

The tactical goal in covert disinformation operations is to intensify existing polarizations within the target polity. Miller reports that the Russian military journal, *Military Industrial Courier*, published a speech by General Valery Gerasimov, chief of staff of Russia’s armed forces, in 2013. Gerasimov outlined the harnessing cyberattack capabilities. “[T]he role of nonmilitary means of achieving political and strategic goals has grown, and, in many cases, they have exceeded the power of force of weapons” (quoted in Miller, 2018, p. 28). The function of social media in enabling what developed into the Arab Spring seemingly demonstrated the practicality of social media for attaining preferred political developments in targeted state actors. “Frontal engagements” by military forces are to become “a thing of the past” (Isikoff & Corn, 2018, p. 44). The St. Petersburg state sponsored covert cyber operations unit, the Internet Research Agency, demonstrated the usefulness of cyber operations as a component of hybrid warfare tactic during the 2016 US presidential campaign. Occupying a four-story building, it produced content that via Facebook reached an estimated 126 million Americans during the 2016 US presidential campaign (Miller, 2018, pp. 36, 181). The degree of American cultural discourse awareness and sophistication in the Agency’s ongoing “Project Lakhta” American polarization promotion disinformation campaign has increased (Ohlin, 2018, p. 22). US government agencies have initiated counter-measures, e.g. the US Justice Department in September 2018 revised policy regarding “Disclosure of Foreign Influence Operations” (Ibid., p. 18).

Social Media and Societal Polarization

Social media internationally has exacerbated polarization surrounding persistent racial, ethnic, sectarian and cultural fault lines because of the features of the social media for-profit business model. Social media account owners choose to receive content from specific distribution lists for particular types of

content, including content that represents itself as news reporting and analysis. Social media distribution relies on algorithmic methods to select and direct content irrespective of truthfulness to designated account owners. Facebook management decided prior to November 2016 to end human oversight of content feeds to users' accounts in order to avoid the appearance of subjective partisan bias to potential advertisers (Miller, 2018, pp. 183-91). These computer software algorithms route posted content according to account holder interest as extrapolated from their collective earlier content viewing choices, likes/dislikes, friends, and other inputs. A consequence has been the magnification of the so-called echo chamber outcome on citizen-consumer perceptions and attitudes that associate with stereotyping (DiFonzo et al., 2014).

During the Reagan administration, the US Federal Communications Commission encouraged this trend in 1987 by abandoning the Fairness Doctrine, adopted in 1949 by the Federal Communications Commission. The Fairness Doctrine required "a reasonably balanced presentation" of alternative political viewpoints, building on the 1927 Radio Act (Lepore, 2018, para. 7). Enforcement was rare (Clogston, 2016, pp. 377-78). The highly-competitive for-profit news media business produces items for consumption that interpret events in accordance with their respective editorial ideological inclinations. The modal citizen-consumer tends to favor news media consumption selections which conform with their existing political perceptions and predispositions. Incongruous information reports and analyses which generate disagreeable emotional reactions due to conflict with these intensely held beliefs and attitudes can much more easily be dismissed. The upshot is to strengthen pre-existing citizen-consumer political assumptions and viewpoints on the range of topics. The vastly larger variety of news sources has greatly increased the ease of self-validation of political self-identity for the media citizen-consumer through finding confirmation in news reporting. They can find seeming endorsement for their pre-existing, strongly held political views from intensely competitive for-profit news media product purveyors. The latter forcefully profess to be current events authorities in their marketing campaigns. They thereby support the citizen-consumer's self-validation while embracing membership in a legitimated community of more or less self-conscious fellow ideologues. Their outlooks incorporate shared implicit and explicit elements of favored worldviews regarding political cause and effect. These worldviews incorporate classification of malign and benign political players and their real or conspiratorially imagined influences. Intense emotional affect associates with stereotypical image formation (Cottam & Cottam, 2001, pp. 99-105). Actors more inclined to nationalistic behavior are more prone to stereotyping and emotional affect (Ibid., pp. 105-21).

Ideological framing of news reports tends to steer ultimately to explicit and implicit inferences regarding consequences for the well-being of the nation of these reported current events (Horton & Brown, 2018, p. 3). The conceptualization and definition of the welfare and even the survival of the nation are defined according to the respective worldview, i.e. editorial angle. Emotional affect among the market share/public audience/citizenry constituency is thus expected to be stimulated. It must be roused; emotional stimulus and satisfaction motivates consumption and citizen-consumer loyalty while contending for subscription and advertising income. The objectivity façade in news reportage must be upheld and homage paid to it as part of marketing for all news items to be propagated for consumption as news reports on current events. Maintaining this citizen-consumer loyalty in a fragmented, diverse collection of ideological niche markets has become a business success imperative. Serving, even pandering to these niche market demands to maintain market share tends to intensify and reinforce these preexisting viewpoints.

This competitive for-profit systemic logic for maintaining media-consumer/citizen loyalty tends to encourage the stereotyping of non-conforming views as not only flawed, but morally reprehensible. Reinforcing political in-group predispositions concurrently intensifies demarcation from out-groups

(Bruchmann, Koopman-Holm & Sherer, 2018). The news media functions figuratively both as an echo chamber for the citizen/media-consumer and also as an amplifier. A positive portrayal of the news media characterizes it as a collection of institutions where the citizen/media-consumer may subject their presumptions to examination via exposure to additional evidence. This ideal view perhaps always has been a positive stereotype. A conventional metaphor portrayed the news media as the “watchdog of democracy” (Orzeata, 2016, p. 135). Another trope depicts the news media as the conduit for the “marketplace of ideas” (Asenas & Hubble, 2018, p. 38). Yet, incongruous information was more difficult to evade or reject in the postwar era under the Fairness Doctrine and with television news restricted to three national networks.

The echo chamber effect is a term that highlights this source of political polarization along with the emergence of the Internet-based social media platform for media product distribution (Matakos, Terzi & Tsaparas, 2017). The growth of Internet social media has magnified and mobilized constituencies around these polarization cleavages, at times with violent, tragic results. E.g., a Sri Lankan militant in 2018 utilized Facebook to disseminate hatred and paranoia leading to an anti-Muslim riot killing one person and making many more homeless. Facebook has become in effect the world’s largest news agency. Hate speech runs rampant on the Facebook news feed because it engages users, intensifying stereotype-based hatred. It thereby polarizes politics through its near limitless communication platform. Neither social norms nor gate keepers generate restraints while Facebook as a company avoids intervening in contentious exchanges, not to mention engage in censorship. Facebook aims to avoid the inevitable charges of bias from particular frustrated viewers/consumers that inevitably emerge if it employed human managers to attempt to moderate content distribution (Miller, 2018, pp. 184-87). Facebook is a market-share and profit-driven company. Facebook is hesitant to adopt policies that would require it to take public responsibility for inevitably controversial decisions that may drive away some viewers/consumers to other social media platforms.

The Need for Plausible Deniability

The originator of disinformation that is external to the targeted foreign polity must not only be hidden. The disinformation should be depicted as a creation of independent constituencies within the targeted society. Black Elevation is an infamous example of a fake activist group portrayed as the source of social media political advertisements attacking the Hillary Clinton presidential campaign (Frenkel, 2018). This particular feature of the covert Internet-based, Russian government-propagated US influence operation exploited already-present US internal polarization surrounding the Black Lives Matter movement. Escalating social conflict by inciting opposing sides concurrently seemed to be the tactical political objective. Investigative journalism reports underlined the efforts by these Russian state actors to keep their operational efforts hidden.

Misinformation operations disguise their propagator so as to prevent construal of the motives of the initiator which could allow for the perceiver’s dismissal of the misinformation as foreign propaganda. The Russian government’s engagement in these activities derives in part from the Cold War genesis of these programs (Allen & Moore, 2018, Abrams, 2016). Long before Internet-based social media, the requirement to declare the source of initiation of an influence attempt by a foreign government is expressed in the obligation to register as a foreign agent. US law enforcement agencies arrested former Trump presidential campaign manager Paul J. Manafort Jr. for disregarding the 1938 US Foreign Agents Registration Act (FARA), among other charges. Manafort concealed the Ukrainian government as his client sponsoring his firm’s lobbying activities on behalf of pro-Moscow (former) President Yanukovich.

Investigation into the 2016 US presidential has revitalized the heretofore desultory implementation of FARA (Farwell, 2018). Whether such behavior is illegal, not to mention criminal, in a particular case is debatable rather than definitively answerable. A particular case's determination would require that a legal actor with standing have the motivation and resources to support ultimately successful legal proceedings in a court of law with appropriate jurisdiction. E.g., until very recently, US enforcement of FARA was somnolent because the issue of influence generation by foreign actors employing US-based representatives was not a highly salient political issue. Consequently, FARA's requirement to register with the US Justice Department was largely ignored. The 2017 indictment and guilty plea of Manafort and others for violating FARA established a new legal precedent. As a result of the US Department of Justice Special Counsel Robert Mueller investigation, one former official in the Clinton and Obama administrations is under indictment for violating FARA. Mr. Gregory B. Craig has also been charged with failing to register as a Ukrainian government lobbyist (Vogel and Benner, 2019).

Public international law requires that persons employed as agents of influence on behalf of a foreign government must declare publicly their representation. "States have always vigorously protested and claimed compensation when foreign States have exercised on their territory public [i.e. state government-orchestrated (BD)] activities that have not been previously authorized. They have also reacted in this way when the public action on their territory had been performed secretly or by State agents allegedly acting as private individuals" [*sic*] (Cassese, 2005, p. 51). Responding to US government pressure, Facebook today mandates that purchasers of ad space for political purposes confirm that they are US citizens or permanent residents. The pressure on Facebook continues. E.g., in late 2018, a gap in Facebook's new ad policy continued to permit advertisers to fill the "paid for by" field in their advertisements with whatever text they chose. It essentially let them continue to disguise their identity to the viewer. Facebook took the initiative to report externally-based social media influence operations targeting the US 2018 midterm congressional elections as well as other international targets.

Contestants for influence over public opinion in general, and not only international actors, may seek to conceal from view and thereby deceive viewers concerning their instigation of a social action. Political donors may prefer to hide their contributions purposefully if legally feasible: so-called dark money (Ridout, Franz & Fowler, 2015, p. 156). They aim to obscure themselves as the source in order to avoid strategically undesirable interpretations of intent. Thereby, by avoiding disclosure they attempt to generate or support the influence they desire on the audience target of the campaign that they misleadingly support. Research evidence indicates that American voters view so-called dark money, i.e. unattributed campaign financing, as a generally negative feature of a candidate perceived as utilizing such funds (Wood, 2017). Hence, a political candidate for office may seek to obscure their reliance of such campaign resources. Astroturfing is a colloquial term that has become part of the critique of the Internet as camouflage. It refers to misleading attempts to portray grass-roots support online by utilizing the capacities of the Internet to mispresent levels and types of public support for the campaign to the audience. Internet communication generates concern that large organizations disguise their identities to seek "grassroots" credibility for their campaign input in the eyes of their targets, i.e. they "astroturf" (Shafie, 2008, p. 401).

Astroturfing at the international level allows private sector businesses to conceal themselves behind a non-profit, non-governmental organization (NGO) façade, implying broader, humanitarian motivation. It thereby increases their influence within the process of global policy making. Durkee (2017) highlights the challenges of astroturf activism at the international business regulatory level regarding, e.g., tobacco commerce. UN-approved regulations currently forbid for-profit businesses from the formal right of consultancy input into UN international treaty negotiations (p. 206). For-profit corporations manipulate

non-profit non-governmental organizations to mask their covert business input into UN international treaty-making via the formal designation as an UN NGO consultant (Ibid., pp. 243-44). As with astroturfing, this obfuscatory manipulation is not essentially illegal. Such a determination depends not only upon the requirements of a particular legal jurisdiction, but also upon the legal standing, political willingness and financial resources to pursue a legal claim. “Online election campaign speech remains almost entirely unregulated” regarding sponsorship disclosure, illustrating in part the tension with the US Constitution First Amendment’s protection of the right to anonymous speech (Rutenberg, 2019, para. 32).

SOLUTIONS AND RECOMMENDATIONS

First, increase transparency of both governmental and for-profit business influence efforts through international norm-making, e.g. a set of “digital Geneva Conventions” (Sanger 2018, para. 25). “An international lawmaker must be able to identify and rely on the authenticity of the mission the organization pursues in order for the lawmaker to effectively assess that input” (Durkee, 2017, 245). A policymaker should have a plausible opportunity to discern the ultimate, true motivation of an influence organization to evaluate its policy making input. Damage coverage is problematic partly because insurers invoke “war exclusion” to avoid paying costs from cyber combat yet state state-sponsored cyber attackers typically do not publicly declare war (Satariano & Perlroth, 2019, para. 5).

By disguising its real intent or instigation, a political actor in so doing aims to engender the anticipated perceptual and emotional response from the targeted audience (Aakhus, 2016, pp. 202-03). The citizen/media-consumer’s interpretation of the advertisement may otherwise be influenced in an undesirable direction. The perceiver may infer the particularistic, profit-oriented motivation presumed to be motivating a business’ advocacy of a public policy position. Heider (1958[2015]) explained that social actors behave as so-called naïve scientists, prone to attribute and evaluate motives while interpreting the significance of an action by another actor (Harris & Fiske, 2008, pp. 210-11, Körner, Tscharaktschiew, Schindler, Schulz & Rudolph, 2016, pp. 2-3). Judgements concerning the actor’s mental state are intrinsic in comprehending and interpreting social interaction (Vogeley, 2013, p. 297). Political competitors engendering disinformation confront the incentive to disguise their partisan allegiance so that the perceiver is less likely to reject the misinformation for what it is, i.e. partisan propaganda.

According to social psychological concepts of motivational attribution, cognitive dissonance and cognitive balancing, a participant observer will incline subjectively to impute plausible causation to a political act (Pishghadam & Abbasnejad, 2017, p. 137). The concept of transparency mandates cognizance of sponsorship behind a political action. Notwithstanding transparency, the perceiver will likely attribute intent, irrespective of inferential accuracy. Compelling this sponsorship to be public permits the participant observer a plausible opportunity to obtain what they believe to be essential, accurate information. This information is required to attempt plausibly to predict the political consequences of the citizen/media-consumer/participant observer’s own choice of action in response. Through gaining awareness of the source and inferring its motivation, the participant observer interprets the significance of the statement claim. The participant observer accordingly selects their own response to this attempt to persuade this perceiver.

Second, one intent of the European Union’s 2018 General Data Protection Regulation is to restrict the heretofore virtually limitless accretion of individual social media user data. The massive accumulation of this data has been critical for the algorithmic distribution and microtargeting of social media posts. It requires tech companies to receive individual, explicit permission to obtain this private user data. The

activity of covert social media disinformation disseminators would be disrupted, but at a potentially significant collateral damage cost to other lawful and appropriate users, companies and services. Other potential costs include significant barriers to ensuing stages of tech development, including nascent 5G and artificial intelligence-based devices (Radu, 2019).

Third, other proposals include anti-trust action to break up big tech companies such as Facebook (Hughes, 2019). They allegedly now wield monopsony market power that facilitates unethical and illegal systematic and gross privacy data aggregation violations. Covert, hybrid/cyber warfare actors can exploit this aggregated big data for their own particular ends. E.g. Cambridge Analytica, established by a Russian-American academic at Cambridge, constructed social media user profiles from 87 million Facebook users to build microtargeting social media political campaigns. The Trump campaign hired the firm in summer 2016. The April 2019 US Department of Justice report under Special Counsel Robert Mueller on Russian government activity surrounding the 2016 US national elections did not reference Cambridge Analytica (Bertrand, 2019). The perpetually difficult political tradeoffs between guaranteeing security while protecting civil liberties and rights become more complex along with the diffusion of authority over control of information. To resist reasserting this control, obscuring this control becomes politically more desirable. Fourth, a consequent policy response is likely to be a strengthening of the national security establishment's intelligence/counterintelligence capabilities in the form of greater hybrid/cyberwarfare legal competences.

FUTURE RESEARCH DIRECTIONS

Cold War-era American-led influence institutions, e.g. NATO, remain in place. They are developing to respond to new, criminal challenges, e.g. the "cyber ransom attacks" in 2018 against European and non-European institutional targets (Ackerman, 2019, para. 10). US Cold War-era national security institutions command vast resources enabling far-reaching political influence within the US polity. These institutions and their public and private sector support constituencies have vested interests in portraying their existence and role as continuing to be essential for US national security today. These institutions include the covert operations and propaganda bureaucracies that was so much a part of Soviet-American Cold War competition. These assumptions appear to be mirrored in Moscow, i.e. the Soviet-era national security establishment contained the US until poor leadership under Mikhail Gorbachev surrendered to American expansion. Moscow today must use all tools at its disposal to reconstitute its containment effort towards Washington. These tools include Cold War legacies including covert subversion and propaganda capabilities in what is now called hybrid/cyber warfare.

Controlling escalatory crisis dynamics to avoid direct military great power confrontation is essential in the nuclear era. Covert cyberattacks are practical in the nuclear environment because they can be effective and costly to a target but determining their source is problematic and requires much time. Determining responsibility is difficult because indisputable public evidence of the origin of an assault is likely to be lacking. E.g., neither the US nor Israel have confessed to the Stuxnet cyberattack against Iran's nuclear fuel weapons-grade enrichment program, which the Iran authorities never admitted existed. In an illustration of the dangers of blowback, the Stuxnet malware through the Internet then contaminated computer systems outside Iran (Denning, 2012, p. 676). Undeniable evidence of a Pearl Harbor-type surprise cyber-strike would likely generate a nationalist public opinion reaction. Government leaders would then confront the political imperative to select a subjectively determined proportionate response in the era of mass politics. Questions of responsibility remain regarding the destructive 2014 covert

cyber-attack against Sony Pictures Entertainment following release of a film caricature of an assassination plot against North Korea's leader (Brunner, 2017, p. 3 fn. 28). The Obama administration promised retaliatory cyberattack countermeasures but did not specify what they would be or when they would occur (Sharp, 2017, p. 912). Porous state borders in the era of globalization in its latest manifestation in the form of the Internet have expedited intervention in the internal politics of target polities. A likely consequence is the strengthening globally of the intelligence/counterintelligence capabilities and flexible reprisal instruments of the national security state that emerged in the twentieth century in the midst of global conflict.

CONCLUSION

Covert propaganda and influence efforts were a very important part of the so-called Cold War. The US self-perceived success in the containment strategy has led to assumptions and behavior that underplay the progenitors of what is today called hybrid warfare including its cyber component. Covert propaganda disinformation campaigns are not new. Internet social media is new, but it is merely a new vehicle for a familiar policy pattern. The prevalence in the scholarly and news media discourse of heightened alarm regarding so-called hybrid warfare is worthy of research. As noted, the US and the USSR and other actors engaged in this covert, hybrid warfare activity extensively during the Cold War. The collective, selective perception of historical behavior arguably reflects an unwillingness of many in the US to recognize that the US engaged in this form of polarizing activity. Covert propaganda campaigns are hybrid/cyber/dark web warfare when the enemy uses them.

KEY TERMS AND DEFINITIONS

Cold War: Intense bipolar international competition for influence and control between the United States and the Union of Soviet Socialist Republics (USSR). It began at the close of the Second World War and continuing until Soviet-installed communist regimes collapsed in Eastern Europe in 1989 and the USSR itself disintegrated in 1991. This conflict was labelled cold because nuclear weapons made direct military combat between the two likely to result in mutual suicide through escalation to so-called mutual assured destruction. The US and the USSR and their allies and clients therefore competed indirectly through competitive interference in the internal politics of third actors. The Cold War established the template for international conflict between nuclear powers. The cause of US and Soviet conflict is still debated; some argue it was due to mutual fear, others argue that one or the other was bent on imperial expansion, and still others argue that both were bent on imperial expansion. The politically prevailing view in the US today is that the US prevailed over the Soviet Union in the Cold War. Consequently, American-dominated Cold War-formed institutions such as NATO are positive tools for international stability and peace. They should be expanded and adapted to changed circumstances.

Globalization: Increasing global awareness of economic, social and political interdependencies among states due to increasingly porous state barriers due to rapidly increasing commerce, finance, information and labor flows across these borders. Incentives to globalize ultimately relate to the imperative to develop a state's economic and political power resources through integration in the global capitalist production chain.

Hybrid Warfare: A recent term for reliance upon covert and informal policy tools for interference in the internal politics and policy making in target states. This term emerged concurrently with the development of the Internet as an infrastructure vehicle and as form of media communication. Covert and informal modes of international political competition and influence expansion acquired greater emphasis along with the post 1945 nuclear setting. The need to maximize the degree of control over potentially escalatory conflict dynamics pushed policy makers to obscure their international victories, defeats and stalemates in order to lessen the potential for provoking nationalist hostility that would lessen the political decisional latitude available to policy makers.

Nation: A community which a nationalist believes should and can achieve national self-determination through acquiring a sovereign state for the nation if it does not already have such a state. If this community already has its own sovereign state, then the nationalist will be perceptually and emotionally preoccupied with challenges to this sovereign state, tending to equate the state, represented by its governmental apparatus, with the nation.

Nation State: A state in which the overwhelming majority of citizens show their primary self-identification with the territorial community within the state through favoring it more above any other identity group or community. Examples include the United States, Russia, China, Japan, Germany and others. Multinational states, such as the old Soviet Union and Yugoslavia as well as Iraq, are not nation states. Neither are multiethnic states nation states. Examples of the latter include most post-colonial African and many post-colonial Asian states including India. Non-nation states, and multinational states in particular, are subject to centrifugal political forces among ethnic groups seeking national secession and self-determination. These centrifugal forces may maintenance of liberal democratic political regimes highly problematic insofar as democratic elections produce ethnic nationalist leaders seeking self-determination. The communities of the old Yugoslavia as well as in the old Soviet Union continue to deal with such secessionist and irredentist nationalist forces.

Nationalism: A form of intense ingroup political loyalty opposing perceived challenges to the sovereignty of the nation. It is characterized by relatively intense emotional affect and perceptual stereotyping of self and other, outgroups stereotypically perceived as challenges to the nation. A community behaves nationalistically when the modal, politically attentive citizen is a nationalist.

Nationalist: An individual who sees himself/herself as a member of a large group of people who constitute a community that is entitled to independent statehood and who is willing to grant that community a primary and the primary terminal loyalty.

Polarization: Intra-societal stereotyping due to intensifying perceived challenges from other constituencies within a polity, with the different contestants portraying the other as disloyal, even treasonous, to the nation and its state. Polarization is most likely to intensify when certain constituencies within the polity portray their favored policy prescriptions for the perceived well-being of the nation as religiously, i.e. divinely mandated. Secular opponents, therefore, are more likely to be stereotyped as evil and disloyal.

Power: The exercise of influence over the minds and actions of others.

Stereotype: A simplified perception of the political environment, specifically regarding policy targets. Differences in stereotypical patterns in perception emerge along with different types of perceived challenges to the perceiver from a target. An intensely threatening target of perceived equal capability and techno-cultural level will tend to be perceived as a diabolical enemy. A perceived weak, inconsistent and unmanageable target unable to resist the perceiver's greater will and determination to achieve its objectives will tend to be perceived as degenerate. Dangerous adversaries perceived as superior in capability and techno-cultural capabilities will tend to be perceived as an imperial threat. Perceived weaker targets in capability and culture ripe for exploitation to achieve some other overarching objective, i.e. containment of a great power enemy, will be perceived as a colonial target of opportunity. Troublesome, threatening weaker targets in culture and capability will tend to be perceived as criminal rogues.

The Spy Who Never Has to Go Out Into the Cold

Cyber Espionage

Laura Pinto Hansen

Western New England University, USA

INTRODUCTION

Cyber espionage is a fairly recent newcomer to means by which to steal trade secrets, classified government information, or consumer information. However, with the rise of the digital age beginning in the late 1950s, increasingly more documents are stored on mainframe and individual computers than compared to storage in conventional file cabinets. In fact, it is very unlikely that many institutions store files these days on physical shelves, save older archives. Even then, the art of archiving reached the digital age some time ago. This has been exponentially so since the beginning of the Big Data age of the 21st century. In this chapter, we explore the types of cyber espionage, recent cases, as well as challenges to detecting, controlling cyber thievery and mayhem.

It is because of the vast amounts of data that are stored more efficiently on computers and in cyberspace, that these became the new frontiers for spies. Banks (2017, p 513) observes that “it seems that everyone is eavesdropping on everyone else...” Gone is the heyday of trench coat wearing spies wielding mini spy cameras in corporate headquarters, the stuff of Hollywood movies. Dark alley, middle of the night transactions, passing microfiche, audio tapes or video, or files, became increasingly unnecessary with the ease and speed of computer technologies.

A circular tautology exists: Technology has always created new advances in warfare (Roberts, 2017) and new advances are created during times of war, including in those conducted in cyberspace. Even art imitates life, with movies depicting elaborate fictional cybercrimes that are not so far-fetched. A handful are even based on true cases, as in the 2013 movie, *The Fifth Estate* (DreamWorks), depicting the infancy of the website, WikiLeaks.

Spying is considered business as usual in international relations, though nations publicly deny that they are involved in espionage. State-sponsored surveillance is common place and considered to be a necessary evil in order to maintain world order and promote national security. This challenges the principles of democracy and privacy. State-sponsored surveillance has its critics (Schmitt and Vihul, 2017). Comparisons have been made to George Orwell’s 1948 novel, *1984*, where Big Brother is always watching: “If you want to keep a secret, you must also hide it from yourself.” (Orwell, 2017, p 283)

On the other side of the argument, surveillance is argued to be a necessity in order to detect cyber attacks (Nissenbaum, 2005). The consequences of cyber intrusions by perceived hostile nations or “frenemies” (nations who are friendly for purposes of trade relations, but secretly economically and militarily compete with) are far reaching. As much as state-sponsored surveillance of governments is

commonplace, surveillance and cyber espionage are more likely to have an effect on the average citizen, much like other forms of white-collar crime, as compared to conventional crime. In many respects, there is far greater financial and political damage to be done in this day and age, because of the alarming amounts of sensitive information that is stored digitally.

More recent attention has been given to the ability to plant false information through the Internet, in order to engage in propaganda designed to confuse or divide nations' citizens. There is also the greater concern that whole cyber infrastructures could come tumbling down, with the ability of cyber spies or amateur hackers to infiltrate systems for purposes of sabotage, including energy and transportation.

DEFINING CYBER ESPIONAGE

As Randall Dipert (2013) argues, the terms “cyber attack” and to some extent, “cyber espionage” are loosely interchangeable, used to cover a wide range of cybercrimes. We should be clear that cyber espionage is more commonly thought to be limited to the theft of military or government secrets. A subset of cyber espionage is economic espionage, sometimes called industrial espionage, where governments attempt to gain information from foreign companies (Banks, 2017). A cyber attack or cyber warfare, on the other hand, implies that the act is for the purposes of bringing down whole systems, as in the example of viruses transmitted by bogus links imbedded in spam email.

One common means by which to obtain information from individuals is phishing. It is not restricted to attempts to gain personal financial information from employees. In recent decades, the use of company email exchanges has commonly been used to gain access to intellectual property and industry secrets. These are not easily detected schemes, as compared to the notorious Nigerian email scams. Increasingly the emails appear to be generated from legitimate sources, addressing employees by name within an organization, rather than the generic “Dear Sir or Madam”. Sometimes initiated on the Dark Web, it is an effective way to gather information without hacking into sophisticated computer systems that might be heavily protected by more sophisticated cybersecurity systems. And because many are distributed through the Dark Web, the origins of the emails are difficult to detect. The Dark Web allows users to mask not only their identities, but their location.

Cyber espionage is not always limited to the theft of intellectual property. Espionage can also involve subterfuge where false or misleading information is planted. The most common current means by which to do so is through social media, including Facebook, Twitter, Instagram, and YouTube. Though these social media platforms have battled regulatory agencies to offer open access with few limitations, increasingly they have been asked to take a more active role in preventing foreign agents, acting as internet trolls, from agitating users, particularly during election cycles.

An additional form of cyber espionage is the use of malware for intelligence gathering and sabotage. These might not be isolated incidents, but rather can be ongoing campaigns by their designer, attacks presenting themselves within an advanced persistent threat (APT) (Wangen, 2015). Malware can come in a number of different forms, including temporary nuisances, as in the case of “bugs” or having far more devastating result, as in the example of a “Trojan horse”. More commonly in cyber espionage, the use of spyware allows for information to be collected from individual computers, including keystrokes to obtain passwords or gather information about use. The lesser known, but in many respects, deadlier “rootkit”, allows the user to evade detection and has the ability to alter software, including security systems.

Unlike the stereotype of the lone hacker or spy working from some dank basement apartment, much of what is occurring is within criminal networks. Social network theories are excellent tools in order for researchers to understand the mechanics, beyond the technical, of how cybercrimes, including espionage, are executed (Schaefer, 2014). The targets of criminal networks conducting cyber espionage vary and can include a number of illegal activities. Some of the types of illegal activities can be found in Table 1.

The fact that cybercriminals can operate within a network, once detected, they run the risk of exposing other members of the network to detection. However, as is the case with criminal and legitimate social networks, the boundaries of a network can be vague (Hansen, 2009). This makes it difficult for law enforcement agencies to capture every actor within an illegitimate network. What is particularly challenging and aggravating to investigators is that criminal networks can be embedded within legitimate networks (Hansen, 2009).

Historically, a criminal is physically present at the crime scene (Speer, 2000), allowing in some cases for law enforcement to apprehend a perpetrator on the spot, catching them in the act. This is particularly true in undercover sting operations. Now a corporate or government spy doesn't even have to leave their home, much less their country, to gain access to digitally stored information. This has never been more evident than with the infamy of Julian Assange, mastermind behind WikiLeaks, an international non-profit organization dedicated to publishing classified documents and information for alleged altruistic reasons and purposes of government transparency. Though arguably, detection is not impossible, and may cause the perpetrator to go on the run to avoid capture. As a direct result of Assange's activities, he is man without country at the moment, holed up in the Ecuadorian embassy in London as of this writing. But his nomadic existence does not stop him from continuing his operations.

CYBER ESPIONAGE AND INTELLECTUAL PROPERTY RIGHTS

There is an ongoing battle between advocates of the preservation of intellectual property rights and the demand for freedom of information by others. This is especially typical in democratic societies, as exemplified by the Freedom of Information Act in the U.S. (FOIA). As we have shifted from an industrial

Table 1. Seven forms of information warfare

TYPE	DESCRIPTION
Command-and-control	Attacks on command centers or commanders themselves to disrupt command effectiveness
Intelligence-based	Increasing your own situational awareness while reducing your opponent's
Electronic	Using cryptography and degrading the physical basis for transferring information
Psychological	Propaganda to demoralize troops or influence civilian populations
Hacker*	Exploitation of viruses, etc., to attack computer systems
Economic Information	Possessing and being in control of information leads to power
Cyber	Information terrorism
*We should note that the term "hacker" is now used to include individuals who infiltrate computer systems legitimately, the so-called "white hats", to understand and detect vulnerabilities.	

Sources: Libicki, 1995; Robinson et al., 2015, p 7

economy in the U.S. to an economic dependence on the buying/selling of information and services, it has been a daunting challenge to protect the intellectual property rights of individuals and corporations.

For all the legal considerations, a war is being waged between advocates of open, free-flowing access to intellectual property and those who argue that intellectual property should be protected. Intellectual property can include copyright protected materials, patents and research that is in its infancy should be closely guarded in order to give credit where credit is due. For example, a pharmaceutical company would not want released to the public the results of drug trials in advance of Federal Drug Administration (FDA) approval or rejection. Stock prices rise and fall on the basis of the success (or in some cases, failure) of drug trials.

To further complicate matters, the divide is between the desire for accountability and the demand for privacy (Moore, 2017). In an age of personal information being commodified, bought and sold on the open market, some question whether the concept of privacy has met its extinction in the 21st century. Standing in the way of free access is a litany of U.S. copyright, patent, and trade secret laws (Moore, 2017) that may or may not make sense in a contemporary free-market system.

This begs the question as to whether the stealing of trade secrets is quasi-legal, similar to the ambiguity of insider-trading regulations. Clearly the theft of industrial secrets outside of those associated with national security are more likely to cause financial loss rather than threatening government institutions, except in the case of the defense industry. As much as financial losses can be devastating, of graver concern is the protection of industrial secrets and information associated with military equipment and personnel. Hence the paramount drive to protect intellectual property that involves national security, in spite of claims that all intellectual property should be freely open to the public, not only at the expiration of copyrights and patents.

Further support for the claim of ambiguous regulation is that digital piracy has been difficult to specifically define, much less regulate. Earlier definitions of piracy only included the illegal duplication of computer software (Higgins, 2014; Koen and Im, 1997; Straub and Collins, 1990). However, more recent definitions include a number of crimes, including the theft of digital documents and digital audio or video that is copyrighted (Higgins, 2014).

Speculating on the merits of protecting intellectual property rights is all well and good. However, putting this in context of a global market with global competitors, international attitudes towards rights vary. In some cases, the adages “all’s fair in love and war” and “what is mine is mine; what is yours is mine, if I can take it away from you” makes some intellectual property laws impotent. It has been estimated that upwards to 25% of computer software alone is pirated in the U.S.; on the high end, 81% is pirated in Thailand, with the mean global piracy rate at 36% (Moore, 2017). And that is just in one industry. This represents billions of dollars (USD) lost in software piracy alone, not to mention legal costs when pursuing justice through civil court systems.

Of greatest concern about the loss of intellectual property is the maintenance of stable world order. Scholars and practitioners argue that countries must develop and maintain means by which to preserve international legal order, to assure that security and stability are maintained (Schmitt and Vihul, 2017). There is little understanding of how international law prior to the computer age can be applied to emerging technologies. The institution of law is slow moving, whether interpreted by national or international standards, and cannot necessarily keep up with the rapid march of new technologies. The old adage (Schmitt and Vihul, 2017, p xxv), “*inter arma enim silent leges* – ‘In times of war, the law falls silent’” may apply here as well, as some would argue that we are currently in the age of ongoing cyber wars. But it begs the question, can a cyber attack that includes the theft of intellectual property be considered an “armed attack” (Roberts, 2014) warranting the self-defense of the targeted victim?

TARGETS OF CYBER ESPIONAGE

Cyber espionage targets include a wide range of economic sectors, including energy, finance, IT, aerospace, and biotechnology (Nakashima, 2013). Currently the United States, as one of the economic leaders in the world, is perceived to be the biggest target of cyber espionage. Though certainly it is not the only country that has more recently had to deal with theft of intellectual property or cybersecurity breaches. For example, Tibetan institutions have also been on the receiving end of cyber espionage, as China views cyberspace a strategic platform on which to level military imbalances (Delbert and Rohozinski, 2009). Nevertheless, the U.S. has been repeatedly been targeted by China and others.

The U.S. is not simply an innocent victim of cyber espionage. The United States, along with Russian and China, are viewed as possessing the most technically advanced cyber spies. As noted elsewhere in this chapter, cyber espionage is part of the new Cold War fought in cyberspace.

Individuals, including journalists and politicians, are also seen as targets for surveillance, sometimes by their own governments. There is the expectation that there will be more attacks on and surveillance of individuals by nation-states, as alleged in the case of Saudi journalist Jamal Khashoggi (CSO, 2018).

It cannot be assumed that just because a country allows limited access to the Internet within its borders that cyber espionage can't or doesn't take place. Though more rural locations may have no or limited access to the Internet, governments are assumed to be highly connected. And not all cyber espionage is conducted through more transparent network means. As long as there is a black market for sensitive information, transactions will continue to take place on the Dark Web, an underground network existing on the Internet that requires more sophisticated software and authorization to gain access, offering anonymity to users.

Organized crime is also a contributing factor in cyber espionage. Organized crime, is operating both on the streets and in cyberspace, and function like legitimate, bureaucratic business structures. The fact that cyber conspirators in organized crime are now scattered across the globe allows for more flexibility in operations (Fielding, 2017). As noted earlier, social networks are a natural conduit in which to conduct criminal acts, including organized crime in cyberspace.

Though organized crime groups are ordinarily thought to deal in conventional victimless crimes like loan sharking, drugs, and prostitution, by definition, any group that is powerful and is able to conduct sophisticated criminal operations, including cybercrime, can be considered part of organized crime. And as cybercrime, including espionage, is so lucrative, it makes sense that more traditional organized crime groups would look to see this as the new marketplace for illegal activities, operating as a "cyber mob" (Armerding, 2015).

Universities, especially those focus on research (e.g Massachusetts Institute of Technology), are increasingly more vulnerable to cyber espionage. As universities are viewed as industry partners in a number of sectors, including national defense and biomedicine, they are a ripe target for attack from an insider or outsider. More commonly the threat is to student data, including social security numbers. Because of the number of international students attending prestige, Tier 1 research institutions, there is the risk for students and even faculty in all fields to steal science, including unpublished research (Reisch, 2018). With China's military apparatus cited as one of the biggest culprits, there are hundreds of thousands of attempts made to breach university systems on a daily basis (Rogers and Ashford, 2015).

CYBER WARS

2

Cyber warfare, along with a number of topics discussed in this chapter, is difficult to define. In fact, the term is very broad and may include a number of different types of attacks, including intelligence-based, and information terrorism (Libicki, 2016; Robinson et al., 2015). A comprehensive list of Libicki's typologies of cyber warfare can be found in Table 1.

One of the chief concerns of all nations beyond protection of classified information, is national security of any and all infrastructures that are dependent on computer technology. Cyber espionage can include sabotage. There is the real possibility that a foreign government could hold another country hostage by infiltrating or destroying critical computer infrastructures. Everything from electric grids to flight operations are controlled with computers and the fear is that sooner or later, instead of a nuclear attack, a country could come to a full stop by a cyber attack. And cyber attacks on infrastructures have the potential of doing far greater long-term harm, than in the cases of garden variety viruses or unauthorized computer break in, as these take longer to recover from (Nissbaum, 2005).

Additional serious concern is any cyber attack that specifically target transportation or energy, is that government agencies, industries, medical facilities, and first responders are dependent on these being up and running at all times. Emergency response teams have a challenging time responding to natural or human-made disasters, even when transportation and electric grids are minimally impacted.

So far, devastating human generated attacks that have the potential of directly affecting millions of citizens have been thwarted on the most part. A successful large-scale attack is not an impossibility, as in the example of the 2015 service outages in the Ukraine, that Ukrainian officials attribute to Russian security services, (Lee et al., 2016). The belief is not *if* a widespread power outage due to cyber attack will happen, but *when* and *where* it will happen. Large scale attack could throw a portion of the world into 19th century conditions, something that some governments and most individuals are ill-equipped to handle. Fortunately, due to the interdependency of the world economy where it would not be in nations' self-interest to engage in widespread cyber warfare, it is unlikely that this will happen in the foreseeable future.

More recently attention has been given to cyber espionage and warfare in the form of political propaganda and manipulation, as in the ongoing Robert Mueller investigation into alleged election tampering and voter suppression. Mueller was named by the Justice Department to head the FBI's special counsel investigation of the 2016 Presidential election in the United States. Allegedly, at the time of this writing, the espionage was being condoned by highly placed individuals in the Russian government. Beyond the leaking of supposedly compromising information about Hillary Clinton, Donald Trump's opponent in the election, there is currently an investigation into other alleged improprieties, including cyber espionage. As of this writing, a comprehensive report from the Mueller team is pending and the investigation is ongoing.

Is it even possible for social norms, beyond laws, to control free speech that is aimed at political manipulation and fraud? There is the misguided trust that all internet consumers can distinguish between what is fact and what is fiction. A Pew Research Center study found that 64% of American adults believed fake news stories during the 2016 election campaign cycle, with 23% reporting that they shared the stories online (Anderson and Rainie, 2017). Because of these events, democratic governments are now taking an active role in holding social media outlets responsible to curb any interferences that might influence the outcome of an election.

Though changes in technologies create new challenges to the First Amendment rights to free speech and free press, this does not mean that efforts to protect it should be abandoned. Wu (2018, p 550) cautions that “we need recognize the role and, indeed, the duty of those who enforce the laws to uphold the First Amendment by defending the principal channels of online speech from obstruction and attack, whether by fraud, deception, or harassment of speakers.”

In light of the current Mueller investigation and the rise of concerted efforts to infiltrate social media, including Facebook, during elections, the First Amendment rights to free speech and free press, as they are currently spelled out in the U.S. Constitution, are being questioned. With its original intent restricted to print media, the uncharted territory of whether it should apply to the more insidious speech filtered through social media. Though it could be argued that this is not decisively different than yellow journalism of the early 20th century, just more widely consumed. As always, the jurisprudence of the First Amendment is caught between the proverbial rock and a hard place.

COSTS OF CYBER ESPIONAGE

As in the case of white-collar crime in general, the financial losses to individuals, banks, corporations, and governments far exceeds the losses from conventional crime. Estimates run in the tens of billions (Nakashima, 2013). Estimates from global cyber activity are losses of between \$300 billion to \$1 trillion (USD), with \$24 billion to \$120 billion (USD) attributed to the U.S. alone (Center for Strategic and International Studies, 2013). In addition to direct costs, there are the exorbitant costs associated in securing networks and hiring cybersecurity personnel, not to mention updating and upkeep of software.

Beyond direct and indirect monetary losses and costs, cyber espionage results in the loss of untold volumes of government and business information, including military secrets, intellectual property and data on customers. A list of high-profile cases of cyber espionage can be found in Table 2. In some cases, loss of intellectual property can negatively affect stock prices for publicly traded companies. In other cases, the real costs, monetary and otherwise, are unknown, including costs to national security. As in other types of white-collar crime, cybercrime can also tear at the social fabric, creating distrust in governments and economic institutions. This has certainly been witnessed in a number of thefts of customers' financial information in recent years from retail companies in the U.S., including Macy's and Sears department stores.

CHALLENGES TO INVESTIGATING AND CONTROLLING CYBER ESPIONAGE

There are a number of ongoing threats to cybersecurity, as well as new ones looming on the horizon. With the growing popularity of authentication, it is predicted that biometric hacking in healthcare, government, and financial institutions will be on the rise (Nadeau, 2018). Encryption alone does not prevent cyber spies from obtaining sensitive information. The Deep Web, that theoretically acts as a locked vault for financial and personal information, does not guarantee that data will not be stolen, as in the examples of identity theft and financial data.

Table 2. 10 biggest cyber espionage cases

YEAR(S) DETECTED	TARGET	CRIME	SUSPECT(S)
1999	Wright Patterson Air Force Base	Stolen American military research documents	Russians, but no proof
2003-2007	U.S. government computers	Stolen intelligence	Chinese military hackers
	UK defense ministries		
1997	Design technology	Stolen intellectual property	Steven Louis Davis
2012-2017	Personal information of government employees	Cyber attack	Allegedly Chinese Government
2010	Google, including Gmail accounts	Stolen intellectual property	Allegedly Chinese spies
2009	Computers in 103 countries,	Unauthorized access	
	Foreign ministries and embassies	Cyber attack	Allegedly Chinese government
2011	European and American energy businesses		Chinese hackers
2008	Computers of the two presidential candidates	Data leakage, cyber attack by computer virus	Allegedly Chinese or Russian hackers
2009	Intelligence on next generation fighter jets	Stolen data	Computers located in China
	Electronic and maintenance information		
2006	A number of international companies	Distribution of malware, stolen intelligence	Allegedly Chinese spies
	and organizations		

The ongoing concerns of cybersecurity are not limited to law enforcement and regulatory agencies. Though cybersecurity is an exponentially booming industry, an understanding of what cybersecurity exactly entails is still not clear (Parekh et al., 2018). And as the government, corporations, and institutions (e.g. colleges and universities) may be constrained by budgetary concerns, they may not be able to purchase ample cybersecurity nor hire adequate numbers of specialists to maintain and monitor systems in place.

It is particularly important to note that as in the case of conventional crime, resources for combatting cyber espionage are focused more on control rather than prevention. As Speer (2000) noted during the infancy of cybercrime research, domestic and international security agencies shifted attention away from espionage towards transnational criminal threats, including drug trafficking and organized crime, after the Cold War, as they became more high profile. This left vulnerabilities in the prevention of cybercrime, as resources were spread thin elsewhere.

One key to investigating cyber espionage is to not only understand computer networks but also understand the uses of social networks to commit cybercrimes. Exploitation of unsuspecting victims is predicated on developing trust relationships. More alarming is that espionage activities are not limited to relationships between sophisticated, trained spies. During the 1990s, an Israeli operative helped a couple of teenagers in California interfere with military deployments (Speer, 2000).

An act of espionage is not always an outside job. As in the case of traditional espionage practices, trusted employees are still utilized in order to steal secrets (Duckworth and de Silva, 2016). A second critical issue beyond the extent that social networks play a part in espionage activities, is the concern that blackmailed personnel may give up trade secrets or sensitive information. It is the very reason that individuals who handle sensitive data are asked to undergo extensive background checks, including investigation into financial history, as someone who is in serious debt or financial trouble can be made a target of blackmail or corruption.

Blackmail is, per se, nebulously illegal, as in the case of other victimless crimes (e.g. prostitution). Even though the blackmail target may feel that they have no choice but to comply with the blackmailer, it is a relationship that is viewed to have been entered into voluntarily, between consenting adults (Block, 2000). Unless the targeted victim comes forward to authorities, blackmailing activities can be ongoing. There is little incentive for the victim to come forward, as in the process of paying the blackmailer in embezzled funds or information, as they may very well be committing a crime themselves.

An additional weakness in cybersecurity is that there is a tendency towards general deterrence that does not always help in protecting systems against specific threats. As Duckworth and de Silva (2016) caution, security personnel are more likely to take an agnostic, whole system approach to protection, with less focus on who or what is threatening their systems. However, in the defense of security experts, it is a challenge for cybersecurity specialists to keep up with the vast number of means that cyber espionage can be accomplished, much less the direction it is coming from. This is particularly true with the ability to conduct cyber espionage anywhere with the country of origin in question.

An additional major drawback in investigating cyber espionage is that a growing number of cases involve foreign governments, making detection and regulation challenging, not to mention diplomacy. And because regulation requires legislation, by the time that laws have been enacted, some have already become obsolete, particularly those that target specific types of cybercrime. There is the question of cooperation and challenges to jurisdictional law when trying to control cyber espionage that crosses international borders. As we have witnessed in the Assange case, it is not always easy to stop theft and bring the accused to justice, when foreign governments do not cooperate in doing so.

Recent research indicates (Haider, 2018) that there are some countries that may wittingly or unwittingly contribute to cyber espionage by the nature of their legal systems. It is no secret that embassies and consulates operate with a different set of laws than the national soil that they occupy. However, some countries are more restrictive of the activities operating out of the embassies and consulates of foreign countries. Select countries have even been accused of harboring spies, as in the example of the “repeated claim of Austria being a hot spot of international espionage activities.” (Haider, 2018, p 201)

Beyond complacency of foreign governments, there are some that have a more visible reputation than others for conducting cyber espionage. For example, in 2014 the FBI issued a list of “Most Wanted” Chinese nationals, alleged members of the People’s Liberation Army who were indicted for stealing trade secrets for the benefit of Chinese companies (Banks, 2017). And as noted by Table 2 on the ten biggest cases of cyber espionage, China is allegedly the worst offender, though this may be difficult to prove empirically.

As recently as December 2018, Chinese nationals are being accused by the U.S. Justice Department of a global scheme to steal business and military secrets (Isidore and Gaouette, 2018). Among the charges are stealing names, Social Security numbers, salary information of naval personnel. According to Isidore and Gaouette (2018), efforts to bring charges were aided by a number of countries. The value in global cooperation in combating cyber espionage is in pooling otherwise limited resources.

The good news is that cybersecurity against espionage is not completely impossible. There are a number of measures that are in place, including new laws and agencies to deal with the advances of technology. Additionally, there is more focus on employee training in order to make them aware of possible cyber threats within their organization. Plus, as a growing niche employment market, universities are churning out more graduates in IT and CS specializing in cybersecurity. The Bureau of Labor Statistics projects that there will be a 28% increase in demand for information security analysts in the future, a much faster than average growth rate, as compared to other occupations (BLS, 2018).

One measure, among many, that the U.S. federal government has recently taken, is Executive Order 13010 under President Bill Clinton (1996). The executive order called for strategies to protect sensitive infrastructures from cyberattacks with the creation of the Federal Intrusion Detection Network (FEDNET) (Speers, 2000). However, the focus of the new agency was on malicious activity, rather than on attempts to stem the theft of intellectual property or sensitive government data, as FEDNET is intended to protect cyber infrastructures.

As in the case of white-collar crime in general, employers can also put preventative measures in place, beyond cybersecurity. Though not always within the control of supervisors, compensation packages should be perceived by employees to be adequate and competitive for their professions (Hansen, 2009). Employees are vulnerable to corruption if they believe that they are inadequately compensated by their employers for their labor. Employers should also be cognizant of the informal social network dynamics within their organizations, as these may supplant any formal hierarchy structures (Hansen, 2009). These measures should be the responsibility of not only chief security officers (CSOs), but of supervisors and upper level administrative personnel.

One of the strongest weapons in combating cybercrime is public sentiment. In 2017, Equifax, a company that provides credit information and ratings to lenders, had a major breach where approximately 150 million people may have had their personal data exposed. With a number of breaches of credit card information in recent years, the public is much more aware of the risks of having their personal data stolen, resulting in demand for secure data. This does not translate to greater demand for cyber security to prevent the theft of intellectual property. However, public sentiment is predicted to drive data protection policies and pushes for more regulation (CSO, 2018).

FUTURE RESEARCH CONSIDERATIONS

The weaknesses in thinking about the direction that cyber espionage research should go are the same as with white-collar crime research in general. Much of what we can do researching this niche of white-collar crime is to mine news accounts, within historical context, or anecdotal ethnography. Prediction and prevention are near impossibilities, beyond general cybersecurity, making inferential research problematic. The crux of the matter is that as soon as the latest methods by which cyber espionage is committed is discovered, the perpetrators are cooking up newer, better technological *modus operandi* by which to infiltrate vulnerable computer systems.

For scholars, an additional challenge is in coming to a consensus of definitions, whether discussing cyber espionage, cyber attacks, or cyber warfare. Social sciences are in a unique position in doing this type of research in shaping definitions for future consideration, as there is the necessity to include research from the “hard sciences”, including information technology (IT) and computer science (CS). Any future considerations for research on cyber espionage within criminologist circles should consider including cross-discipline collaboration with scholars in IT and CS.

Certainly, more research needs to be conducted taking a global perspective. The world is increasingly more connected by way of computer networks in the 21st century, even in some of the more remote or less developed places on the globe. More commonly, there are a number of countries with restricted or limited internet access, including North Korea, Egypt, and Iran, that are by no means excluded from more advanced computer technologies. The ongoing drawback in approaching cybercrime from cross-national comparison is that there are a number of countries that are not forthcoming with crime statistics, as in the example of North Korea. Likewise, attitudes towards what is permissible in cyber activities to secure economic viability in the world economy, as well as national security, varies drastically across the globe.

All in all, beyond the practical applications resulting from any examination of cyber espionage, it is a great opportunity to update somewhat stale white collar crime research for the 21st century. We have only scratched the surface in social science research in cyber crime. Scholars and practitioners will have to be equally adaptable to technological change, as the cyber spies themselves are becoming more sophisticated in their methods.

Grey Zone Conflicts in Cyber Domain: Nonlocality of Political Reality in the World of “Hyperobjects”

2

Muhammed Can

University of Minho, Portugal

INTRODUCTION

Living in the age of advanced technologies comes with a price: Witnessing exponential growth in artificial intelligence, software-hardware systems and the cyber domain has rendered problems more ambiguous. The vulnerabilities of states, societies and individuals have become more evident thanks to the advent of these technologies. One of the most challenging manifestations can be seen in the grey zone conflicts which state and non-state actors constantly mobilize in order to show their strength. Given the existence of weapons of mass destruction (WMD) and deterrence among great powers, it is roughly impossible to expect great powers to dare overt sabre-rattling, which would eventually lead to total chaos throughout the world. Therefore, grey zone conflicts or political warfare has become both a lesser evil and low-cost option for rival states. As Mazarr puts it, grey zone conflicts consist of “salami-slicing strategies, fortified with a range of emerging area or unconventional techniques from cyberattacks to information campaigns to energy diplomacy” (2015, p.2).

Russia’s influence operations and alleged interference in the US elections in 2016, Chinese efforts to shift status quo in the South China Sea, Iran’s way of using grey zone tactics via proxies in its immediate vicinity and the pervasive utilization of unconventional tactics by terrorist organizations, notably by the so-called ‘ISIS’, make grey zone conflicts more significant not only for states but also for laypeople, whose lives are affected by these conflicts along a spectrum of severity. These impacts can be easily discerned in the election process, the perception of reality, diplomatic bargains, unexpected interference by major powers (annexation of Crimea through ‘little green men’) and information warfare.

It is evident that the cyber domain is a major part of grey zone conflicts. Cyberattacks on the political campaign of Emmanuel Macron, the Russian-backed hackers Cozy Bear and their ‘Lisa case’ attacks in Germany, the cyber conflict between Russia and Estonia, and Russian influence campaigns in Sweden, Ukraine and Georgia are among the most recent examples of grey zone conflicts in the cyber domain. In the same vein, it is also explicit that these confrontations between rival states have impacted the nature of political realities, which have rendered merely ‘virtual’ the function of conventional democratic practices – particularly in authoritarian regimes – just as occurred in the post-Soviet landscape (Wilson, 2005).

Apart from being in the midst of these conflicts, political realities have become more ambiguous, which adversely affects states, non-state groups and societies. Moreover, these political realities that are particularly manufactured in the cyber domain have become a nonlocal ‘hyperobject’, which simply refers to “genuine nonhuman objects that are not simply the products of a human gaze” (Morton, 2015, p.199). In his seminal book, Morton coined the term ‘hyperobject’ via object-oriented ontology. For

him, hyperobjects represent the coexistence of humans and objects and simply correspond to “things that are massively distributed in time and space relative to humans” (Morton, 2015, p.1). Therefore, a hyperobject might be the biosphere, a black hole, uranium or plutonium, or it might be “the very long-lasting product of direct human manufacture”, all of which have a plethora of features in common (Ibid). Firstly, hyperobjects are vicious, meaning that “they stick to beings that are involved with them” (Ibid). Secondly, hyperobjects pervade high-dimensional space, and their effects can be found ‘interobjectively’ in a space that includes interdependence between the “aesthetic properties of objects”. Finally, they are nonlocal, meaning that “they involve profoundly different temporalities than the human-scale ones we are used to” (Ibid).

Therefore, this chapter primarily seeks to reach possible answers regarding how the cyber domain of grey zone conflicts affects the political realities on the frontlines. It also attempts to reach an appropriate conclusion to determine possible regulations and existing conventions to counter grey zone conflicts in the cyber domain. Finally, it investigates the reality itself – and its manipulative nature – by putting ‘hyperobjectivity’ at the centre in the context of political reality.

MODERN GREY ZONE CONFLICTS IN THE CYBER DOMAIN

Grey zone confrontations are not a new phenomenon; they are “a nuanced form of warfare where antagonists seek limited political victories, as opposed to outright military triumphs that would be easier to identify and respond to” (Matissek, 2017, p.2). What makes these types of conflicts problematic is that they technically occur between the lines of peace and war, which is not in accordance with NATO’s Article 5 threshold or the UN Security Council’s definition of violence of (Echevarria, 2016). In the wake of World War II, major powers have started to use limited force to eschew total disaster. This type of conflict usually comprises diplomatic, information/cyber, military and economic areas (DIME) “to gain influence and leverage or weaken, destabilize, subvert or overthrow governments without resorting to war” (Robinson et al., 2018, p.8).

Grey zone conflicts “have been conducted in the past under such name as ‘political warfare’, ‘covert operations’, ‘irregular or guerrilla warfare’, ‘active measures’ and the like” (ISAB report, 2017, p.1). The term ‘political warfare’ can be traced back to 1948, when it was coined by American diplomat George Kennan in a memorandum. He defines it as “the logical application of Clausewitz’s doctrine in time of peace.” In the broadest definition, political warfare/grey zone conflicts are the employment of all the means at a nation’s command, short of war, to achieve its national objectives. Such operations range from overt actions such as political alliances, economic measures (like ERP – the Marshall Plan) and “white” propaganda to covert operations such as clandestine support of “friendly” foreign elements, “black” psychological warfare and even encouragement of underground resistance in hostile states“(Robertson et al., 2018, p.2). Furthermore, according to the United States Army Special Operations Command (2018, p.2), “political warfare/grey zone conflicts encompasses a spectrum of activities associated with diplomatic and economic engagement, Security Sector Assistance (SSA), novel forms of Unconventional Warfare (UW), and Information and Influence Activities (IIA)”.

Keeping that in mind, the characteristic of grey zone conflicts might include (ISAB report, 2017, p.2):

- Cyber, information operations, efforts to undermine public/allied/local/regional resistance, and information/propaganda in support of other hybrid instruments;
- Covert operations under state control, espionage, infiltration, and subversion;

- Special Operations Forces (SOF) and other state-controlled armed units, and unacknowledged military personnel;
- Support logistical, political, and financial – for insurgent and terrorist movements;
- Enlistment of non-governmental actors, including organized criminal groups, terrorists, and extremist political, religious, and ethnic or sectarian organizations;
- Assistance to irregular military and paramilitary forces;
- Economic pressures that go beyond normal economic competition;
- Manipulation and discrediting of democratic institutions, including the electoral system and the judiciary;
- Calculated ambiguity, use of covert/unacknowledged operations, deception and denial; and
- Explicit or implicit threat use, or threats of use of armed force, terrorism, and abuse of civilian populations and of escalation.

The vast majority of existing studies in the literature examine grey zone conflicts by drawing particular attention to the Cold War (Linebarger, 1948; Lord and Barnett, 1989; Goldstein and Finley, 1996; Pitney, 2001). However, particularly in the wake of the Cold War, most conflicts have become limited and hybrid in their nature due to the increasing costs of keeping boots on the ground (Fish et al., 2004; Smith Jr, 1989; Waltz, 1998). Therefore, the evolving nature of conflict has enabled relatively weaker actors to engage in information warfare, subversion techniques, and the cyber domain of grey zone conflicts (Mazarr, 2015; Schwartz, 2015; Macdonald, 2006).

Perhaps one of the most sophisticated ones is the Russian way of taking “active measures” in grey zones (Darczewska and Zochowski, 2017). As Polyakova and Boyer put it, “the Kremlin’s ‘active measures’ – covert activities aimed at influencing politics, narratives, and policies in favour of Russia’s geopolitical interests – evolved from overt to covert, physical to digital, conventional to asymmetric. The new tools are cheaper, faster and allow for maximum plausible deniability” (2018, p.2).

Apart from Russia, China has also used different tools that are categorized as unconventional means by coining ‘three warfares’ and ‘unrestricted warfare’ under the command of the People’s Liberation Army’s General Political Department to respond to possible challenges in grey zones (Liang and Xiangsu, 1999; Halper, 2013; Stokes and Hsiao, 2013). Furthermore, rogue states and other non-state groups pervasively exploit these power vacuums to compete with political rivals in different regions. For instance, Iran has recently been using ‘action networks’ by “implementing the covert elements of Iran’s foreign policy agenda, from terrorism, political, economic and social subversion; to illicit finance, weapons and narcotics trafficking; and nuclear procurement and proliferation” (Modell and Asher, 2013, p.8).

In the same vein, the most puzzling area of grey zone confrontations is the cyber domain, which might entail unexpected political and societal consequences at the global level. States opt for grey zone conflicts in the cyber domain partly because of their desire to shape perceptions to gain credibility and support for the legitimacy of their political objectives (Forest, 2009). These strategic moves consist of different ‘active measures’ including information warfare, psychological operations, public diplomacy and strategic communication (August, 2016). Russia is arguably the most sophisticated state, with a huge capacity to alter perceptions in different domains through its active measures. According to the US Senate’s Select Committee on Intelligence, “in the past 60 years, active measures became the norm; in the past 20 years, aggressive Russian digital espionage campaigns became the norm too” and finally “in the past 2 years, Russian intelligence operators began to combine the two – hacking and leaking – or digital espionage and active measures” (Rid, 2017).

Russia's strategy to exploit the information landscape includes a wide range of tactics. Ajir and Vailant (2018, p.77) classify these as follows:

- *Direct lies for the purpose of disinformation both of the domestic population and foreign societies;*
- *Concealing critically important information;*
- *Burying valuable information in a mass of information dross;*
- *Simplification, confirmation, and repetition (calculation);*
- *Terminological substitution: use of concepts and terms whose meaning is unclear or has undergone qualitative change, which makes it harder to form a true picture of events;*
- *Introducing taboos on specific forms of information or categories of the news;*
- *Image recognition: known politicians or celebrities can take part in political actions to order, thus exerting influence on the worldview of their followers;*
- *Providing negative information, which is more readily accepted by the audience than positive.*

REVIVAL OF RUSSIAN ACTIVE MEASURES THROUGH CYBERATTACKS AND CHINESE CASE

In 2007, Estonia was hit by unexpected cyberattacks that took down the online services of media outlets, banks and other government facilities (McGuinness, 2017). Unprecedented waves of spam were sent by botnets, and automated online requests swamped servers, which eventually blocked cash machines, disabled communication among government employees and caused news outlets' news-delivery information flows to malfunction (Ibid). The underlying reason behind the attacks was Tallinn's decision to remove a Soviet World War II memorial – which was dubbed the 'bronze soldier incident' – which sparked outrage in the Russian government (Tamkin, 2017).

However, that was not the last Russian cyberattack. A year later, during the invasion of Georgia, it simultaneously conducted cyber action and a military operation by shutting down Georgia's internal communications (Windrem, 2016). The very fact that Georgia is a former Soviet country doubled the Kremlin's sensitivity whilst conducting strategic 'active measures'. Another Soviet successor state, Kyrgyzstan, was attacked by Russian hackers through distributed denial of service (DDoS) in 2009 (Ibid). It initially aimed at shutting down two of the country's four internet service providers (Ibid). However, the strategic point was Russia's demand for the eviction of a US military base, which Kyrgyzstan eventually met in return for \$2 billion in aid from Moscow.

A DDoS was also evident in the grey zone confrontation with Estonia in 2007. As Valeriano and Maness suggest, "these operations flood particular Internet sites, servers, or routers with more requests for data than the site can respond to or process", which eventually "shuts down the site, thereby preventing access or usage (2015, p.34). Apart from that, Structured Query Language (SQL) injection was commonly used by Russian hackers – particularly in the Georgian War in 2008 – to alter the status quo in different contested regions (Carr, 2012). This type of attack "takes over the site for a few hours or days and displays text or pictures that demean or offend the victim site" (Valeriano and Maness, 2015, p.34). Through the SQL injection, the attacker might execute random SQL queries on the backend database server, which is a highly critical application issue, resulting in the loss of all the data stored (Carr, 2012).

Intrusions, which include Trojans and trapdoors, are another major tool in grey zone conflicts to subvert rivals' strategic agendas. They are more targeted, consisting of "unauthorised software added to a program to allow entry into a victim's network or software program" (Valeriano and Maness, 2015, p.34). The Chinese gh0st remote access tool (RAT) – a type of Trojan – is perhaps one of the most significant of them. It was used as a part of cyber espionage attempt by Chinese hackers which affected 1300 computers in 103 countries, including government bodies, media outlets and nongovernmental organisations (Carr, 2012). Speaking of the effects of these attacks in politics – particularly as a grey zone activity – the latest French election would be a proper example, even though there was no compelling evidence whether attacks impacted the election results.

It is commonly known that this type of interventions in the cyber domain is highly related to the situation of 'plausible deniability', which potentially eases the burden of the aggressor state. It might be a part of a specific special operation, a psychological operation (PSYOP) – which directly aims at altering the perception of the target audience (TA), whether it be in war or not – or political warfare in grey zones. It is also significant to stress that the Russian parlance of cyber warfare does not correspond to the conventional definition; rather, it covers computer network operations, electronic warfare, psychological operations and information operations (Connell and Vogler, 2017).

The 'Macron leaks' incident was an explicit instance that entails a huge controversy among post-Cold War rival states. Hours before the election, Emmanuel Macron's political campaign was targeted and attacked by unknown proxies who revealed thousands of Macron's campaign team's emails (Willsher and Henley, 2017). It turned out later that behind the attack was a Russian hacking team, the so-called 'Advanced Persistent Threat 28' (APT 28), 'Fancy Bear' or 'Pawn Storm', who allegedly have a direct link to the Russian military intelligence directorate (GRU) (Hern, 2017). The method used in the Macron Leaks incident was 'spear phishing', which creates fake login pages to entice targeted individuals to enter their usernames and passwords, giving the hackers unlimited access to their confidential information (Ibid).

However, some argue that spear phishing is not a sophisticated method, even though it has successfully impacted high-profile networks (Valeriano and Maness, 2015). Be that as it may, the political reality and its serious consequences are at stake when it comes to considering whether a cyberattack is successful or not in grey zones. For instance, the Russian cyberattack to alter the Ukrainian election result was a direct attempt to change the political reality on the ground. Russian-linked hackers attacked Ukraine's central election commission, deleted key files and implanted a virus in order to change the result of an election in favour of a Russian-backed party (Polyakova and Boyer, 2018). However, one hour before the announcement of the election result, these attacks were detected by Ukrainian security officers (Ibid). Although Ukrainian officials kept these crisis moments under control, Russian media outlets still wittingly reported the fake results, showing the Russian-backed party winning despite the fact that it just had 1 per cent of total votes (Ibid).

Having mentioned that, Russian information operations in grey zones are not limited to cyberattacks. They also frequently use social media and other conventional broadcasting methods. One of the recent examples is the 'Lisa case', which abruptly affected the perception of mobs in Germany in 2016. It was alleged by the media that a German girl with a Russian origin had been raped by several migrants in Berlin, which prompted far-right groups to march against migrants (Janda, 2016). However, in the wake of the tumultuous protests, a teenage girl admitted that she had made up the story of alleged rape by migrants (Knight, 2016).

In the social media landscape of grey zone conflicts, Russia has constantly staged malicious information operations. The most prominent and recent one is the alleged intervention in US elections in 2016. As the US Office of the Director of National Intelligence assessment claims, Russian influence campaign

encompassed a “messaging strategy that blends covert intelligence operations – such as cyber activity – with overt efforts by Russian Government agencies, state-funded media, third-party intermediaries, and social users or trolls” (2017, p.2). In addition to this, Russia dexterously controlled the narratives regarding the downing of Malaysia Airlines Flight 17 and its poisoning of its former spy Sergei Skripal through social media (Bodine-Baron et al., 2018).

It is an unequivocal fact that Russian activities in the grey zone are not a new phenomenon. On the contrary, they trace back to the Cold War period. As the US Department of State pointed out, in 1985, the Soviet Union started a campaign in order to alter perceptions by spreading fake news that claimed the “AIDS virus had been manufactured as a result of genetic engineering experiments conducted at Fort Detrick, Maryland, allegedly to develop new biological weapons” (1987, p.33). What is more bizarre is another report from this period by the US Information Agency which suggested that Russian media had been constantly circulating an accusation that the United States was conducting covert scientific research to develop an ‘ethnic weapon’ that would be able to kill only non-whites (1988).

In the same vein, the Chinese way of pursuing operations in grey zones – particularly in the cyber and information domain – is similar to Russia’s. Chinese strategic thinking with regard to operating in grey zones also traces back to the Cold War period, apart from the fact that its grand strategy hinges upon the tenets of Sun Tzu. At the end of the 1990s, two Chinese military officers coined the term ‘unrestricted warfare’, emphasising the evolving character of warfare (Liang and Xiangsui, 1999). In subsequent years, the Chinese Communist Party, Central Committee and Central Military Commission ratified the concept of ‘three warfares’ that comprise following three major areas: psychological warfare, media warfare and legal warfare (Halper, 2013).

Particularly in the cyber domain of grey zone conflicts, China has allegedly been involved in different attacks. The most critical example was a Chinese attack on US nuclear weapons laboratories in 2007, when attackers made roughly 1,100 attempts to steal data through different strategies, including sending phishing e-mails to staff (Markoff, 2007). And the United States was not alone in being targeted by China: The United Kingdom and its business sector were also at the epicentre of these attacks. According to a 2008 report of the UK’s domestic security service (MI5), Chinese intelligence agencies have constantly attempted a wide range of attacks to hack the computers of British companies in order to blackmail prominent businesspeople over their improprieties (Burns, 2010). In the following year, the UK’s domestic and foreign security agencies suggested that China’s illegal cyber activities in grey zones had become extremely sophisticated, potentially enabling attackers to shut down several infrastructures comprising food, power and water supplies (Hjortdal, 2011).

China is not only using its cyber capability to compete with its ‘archenemies’ but also for its long-term strategic goals, predominantly in the immediate vicinity. Over the past several years, it has attacked Taiwanese government computers, reaching almost 10 million attacks a month (Yu, 2018). Without any doubt, this is a part of Chinese grey zone strategy that directly relates to its protracted territorial disputes. However, some argue that the underlying reason for these attacks in grey zones is China’s desire to outperform the US in the cyber domain while avoiding being looked at as a malicious actor (Starks, 2018).

Contests in the grey zones – diplomatic, informational/cyber, military and economic – are directly related to the intervening status quo of a balance of power or threat. However, how to deal with the legal status of this type of conflict, especially in the cyber domain, remains the million-dollar question. Indeed, how might authorities conceptualise cyberattacks in grey zones? Should they be regarded as state crimes? Which legal framework would be proper to avoid harmful consequences from this type of conflict?

The Legal Status of Grey Zone Activities in the Cyber Domain: The *Jus ad Bellum* and *Jus in Bello* Dilemma

The problem of how to deal with these attacks in the legal framework is highly tricky given the complexity of the nature of grey zone conflicts. These grey areas are not the only thing that creates ambiguity – determining perpetrators within the legal boundaries is extremely challenging. Brooks draws attention to this point by remarking, “We struggle to tell the difference between civilians and combatants. What counts as a protected civilian object in cyberspace? When can a hacker, a financier, or a propagandist be considered a combatant? When, if ever, is it lawful for a state to respond to a non-kinetic attack using conventional military force?” (2018, para.7).

Perhaps the first step toward reaching a legal way out lies behind two legal principles. International law determines two ways to look at wars. The first is *jus ad bellum* – which accounts for ‘justice to war’ – whose legal source stems from the Charter of the United Nations in Article 2 and Article 51, which states, “all members shall refrain in their international relations from the threat or the use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the purposes of the United Nations”, and “nothing in the present Charter shall impair the inherent right of individual or collective self-defence if an armed attack occurs against a Member of the United Nations” (1945).

The second one is *jus in bello*, which accounts for ‘justice in war’ and “governs the conduct of war once it has started” (Greenwood, 1983, p.221). This subdivision of law hinges upon customary law and treaty laws – for instance, the Hague Regulations of 1899 and 1907 and the Geneva Conventions – to adjust the ethics of war. These two concepts are a major part of the Law of Armed Conflict (LOAC), which governs the conduct of armed conflict.

However, it is not certain which concept would be proper to apply to the cyber domain of grey zone conflict simply because of its pending definition. Furthermore, determining at which point in the escalation between rivals these conflicts ought to be accepted as war is still challenging. Even if rivals accept these activities as sabre-rattling or a declaration of overt war, it is still unclear which regulations would leverage the parties’ strategic position. It is also argued in the NATO Cooperative Cyber Defence Centre of Excellence’s manual – also known as the Tallinn Manual – that determining the threshold of cyberattacks in legal terms is highly complicated given the different strategies and considerations of states, including “views on the subject range from a full application of the law of armed conflict, along the lines of the International Court of Justice’s pronouncement that it applies to ‘any use of force, regardless of the weapons employed’, to strict application of the Permanent Court of International Justice’s pronouncement that acts not forbidden in international law are generally permitted” (Schmitt, 2013, p.3).

There are two main competing understandings regarding the possible legal framework for cyber conflicts. Russia supports an international treaty in compliance with the negotiated terms of chemical weapons, whilst the US finds an international treaty unnecessary (Markoff and Kramer, 2009). According to a declaration issued by the White House, “the development of norms for state conduct in cyberspace does not require a reinvention of customary international law, nor does it render existing international norms obsolete. Long-standing international norms guiding State behaviour – in times of peace and conflict – also apply in cyberspace” (Schmitt, 2013, p.3).

Nevertheless, it is obvious that an international cyber treaty – which would directly impact the cyber frontier of grey zone conflicts – is inevitable given the exponential growth in technology. It is also evident that “the great powers will have no good choice but to cooperate and create rules, norms, and standards of behaviour to buttress what will essentially be a new political order” (Forsyth Jr. and Pope, 2014, p.112).

Another significant view is Shackelford's (2009) taxonomy of possible applicable legal frameworks as follows:

- The Antarctic Treaty System and Space Law
- Mutual Legal Assistance Treaties (MLAT)
- Nuclear non-proliferation treaties
- United Nations Convention on the Law of the Sea

Even if these suggested frameworks will be implemented in cyberspace in the near future, there are a wide range of thorny definitions that remain vague in the cyber frontier of grey zone conflicts. For instance, how should we define a breach of state sovereignty during state-backed attacks? Should these attacks be counted as direct intervention, just like physical ones? Possible answers represent different views with respect to the problem of sovereignty. Rule 4-1 of the Tallinn Manual 2.0 suggests that “cyber operations that prevent or disregard another State's exercise of its sovereign prerogatives constitute a violation of such sovereignty and are prohibited by international law” (2017, p.17).

In this Manual, a majority of experts reached the conclusion that regardless of considering the physical damage – such as non-temporary loss of functionality of infrastructure – brazen cyberattacks by states targeting any country should be treated as violations of state sovereignty (Schmitt, 2017). In the same vein, “the rule of non-intervention is a natural derivative of the concept of sovereignty; to the extent that a State enjoys exclusive sovereign rights, other States necessarily shoulder a duty to respect them” (Ibid, p.7). However, this prohibition of non-intervention could be applied to the issues that fall into the *domaine réservé* of other states (Ibid). For instance, cyberattacks that target the results of elections must be regarded as interventions simply because they directly hinge upon the *domaine réservé*, while others – namely, attacks targeting business sectors in order to leverage vulnerabilities and secrets – cannot be assessed as interventions according to international law (Ibid). It is obvious that this line of reasoning is open to exploitation by aggressor states. By the same token, given the interwoven relations between state-related matters and other sectors, it might be naïve to assess cyberattacks in a different context by only focusing on the *domaine réservé*.

Having discussed the ways to tackle grey zone activities in the cyber domain through existing laws and regulations, it is now necessary to explain how these conflicts have the potential to shift political realities on the ground through the lens of ‘hyperobjectivity’.

Nonlocality of Hyperobjects and Political Realities

The post-truth, fake news, deep fakes, the populist rhetoric of far-right politicians, the propagandist agendas of authoritarian leaders and rising discrimination at the international level based on ethnicity, religion and sexual orientation are chronic problems of the post-Cold War world. But as Mark Twain's popular maxim puts it, “History doesn't repeat itself, but it often rhymes,” so it is almost certain that these aforementioned trends are not new (Cowie, 2009). Rather, the most challenging issue facing the world facing might be the complex relationship between technology and politics. It is possible to witness a more multifaceted interdependency in the near future given the recent unprecedented advancements in artificial intelligence (AI), deep learning and computer systems. Perhaps it will turn into a common principle that ‘who controls technology, engineers reality’, which might render politics purely virtual under the control of ‘political technologists’ (Wilson, 2005).

The construction of political reality has been one of the most contested concepts over the decades. In his seminal article, Edelman argues that “the critical element in a political manoeuvre for advantage is the creation of meaning: the construction of beliefs about the significance of events, of problems, of crises, of policy changes, and of leaders. The strategic need is to immobilize opposition and mobilize support” (1985, p.10). Creation of meaning directly depends on the capability of states and non-state actors to represent realities. Regardless of the ethics and reliability of these realities, political actors might leverage in favour of their political agenda, particularly if the balance of power/threat is at stake.

Beyond that, the use of language and symbols is highly significant in altering the nature of political realities (Burnier, 1994). In grey zone conflicts, states have an immense capability to intervene in the nature of reality through the control of information flow, information operations (IO) and psychological operations (PSYOPs).

Therefore, cyberspace is the most susceptible part of these conflicts due to the lack of international norms and rules. Perhaps the most significant point is the ontological problem of how these realities might alter perceptions at the global level. They have surpassed being objects; rather, they have turned into hyperobjects that might ramble on anywhere in the world thanks to the power of cyberspace. Timothy Morton is the first scholar who coined the term ‘hyperobjects’ within the context of object-oriented ontology. He defines “hyperobjects to refer to things that are massively distributed in time and space relative to humans. A hyperobject could be a black hole. A hyperobject could be the Lago Agrio oil field in Ecuador or the Florida Everglades. A hyperobject could be the biosphere or the Solar System. A hyperobject could be the sum total of all the nuclear materials on Earth; or just the plutonium, or the uranium” (2013, p.1). For him, hyperobjects are the product of the current age of asymmetry between humans and nonhumans (Ibid, p.161).

Moreover, the effects of hyperobjects are worldwide, just like those of global warming, even if they cannot be perceived in tangible forms (Ibid). The main problem regarding hyperobjects, however, is, “how can we know it is real? What does it really mean? The threat of global warming is not only political but also ontological. The threat of unreality is the very sign of reality itself. Like a nightmare that brings news of some real psychic intensity, the shadow of the hyperobject announces the existence of the hyperobject” (Ibid, p.32). The reality, therefore, becomes a nonlocal hyperobject (to borrow an analogy from quantum theoretical psychics that refers to the ostensible ability of objects to directly know each other’s states, even when physically disconnected from each other) in line with the exponential growth in technology.

This argument is valid for the grey zone conflicts in cyberspace. Firstly, even if they do not have physical embodiment, their impacts – particularly with respect to the nature of reality – could cause a global tragedy. The aforementioned ‘Lisa case’ and the alleged Russian cyber intervention in the latest French, American and Ukrainian election were about shifting the political reality, along with the attacks on Estonia and Georgia, even though their effects remained limited. In addition, Chinese cyberattacks on Taiwan, the US and other rival countries were also aimed at intervening in the political reality.

Secondly, the asymmetric nature of grey zone conflicts in cyberspace is similar to the proposed features of hyperobjects, which might appear in the guise of post-truth, fake news and deep fakes throughout the world in a different context.

Finally, these attacks have an immense potential to spread unrealities – in the same way that the diffusion of nonlocal subatomic particles does – even though the differences between the contexts of cases might entail various consequences.

Therefore, political realities/unrealities no longer depend only on the use of language or symbols in political rhetoric in this asymmetric age of politics and related issues. Therefore, cyberspace constitutes the most significant frontier for both states and non-state actors to eliminate their status quo in line with their strategic agendas.

Various solutions can be employed to the cyber domain of grey zone conflicts to overcome the dissemination of political unrealities/realities as follows:

- Agreed international regulations are the most significant prerequisite for reaching a more secure environment in the cyber-domain.
- The definition of cyberattacks ought to be completed through the consensus of competing parties in different landscapes.
- Defining which activities are considered as violations of sovereignty under the umbrella of intervention in the cyber domain is highly significant given the tenuous application of *domaine réservé*.
- Information flow must be controlled based on existing laws by detecting malicious accounts and activities.
- There is also a particular need to establish an international organisation to prevent state-backed cyberattacks by identifying perpetrator states.
- To counter disinformation campaigns in grey zones – in both social media and conventional media – the truth should be revealed as soon as possible to limit the disinformation's diffusion and shift the disadvantageous position of targeted states.
- It is also important to note that limiting and discouraging attacks/activities of authoritarian states in grey zones requires reifying a grand strategy, similar to what was stated in the third-offset strategy of the US (Centre for Strategic and International Studies, 2017).
- Apart from deterrent measures – imposing economic sanctions, suspending multilateral diplomatic talks, military drills or pressures coming from International Organisations – the targeted countries should employ offensive tactics and strategies to counter these attacks.
- Improved defensive firewalls – in conjunction with the recent developments in AI, deep learning, software and hardware systems – are another aspect of the cyberspace frontier of grey zone conflicts, as they have been constantly exposed to ATPs, phishing attacks, Trojan horses and backdoors.
- Governments and international institutions should be informed and up to date with respect to possible future attacks and the nature of attacks in grey zones along with the historical aspects of grey zone conflicts.

Further research needs to examine more closely how cyberattacks would impact other frontiers of grey zone conflicts. For instance, to what extent can cyberattacks alter conflicts in other landscapes, such as the economic, diplomatic, military and intelligence domains? Current understanding of grey zone conflicts is too premature to identify the interwoven relations among such domains, although there is a large body of literature with respect to the current strategies of China, Russia, Iran, North Korea and non-state actors. Therefore, further study could compare the long- and short-term effects of these conflicts. It is also significant to note that there is no exact scientific taxonomy regarding grey zone conflicts. Thus, future studies may classify grey zone conflicts – particularly conflicts in cyberspace – in order to determine how existing rules might be applied to a given case.

CONCLUSION

Returning to the question posed at the beginning of this chapter, it is now possible to state that the unregulated cyber domain of grey zone conflicts is highly challenging for democratic countries, considering that their counterstrategies are restricted by domestic laws. Perhaps Russia is the most capable country in grey zones – in different domains – given the fact that it has engaged in constant interventions since the communist revolution took place. The latest activities in Ukraine were unexpected and unusual for Western countries. China is the second country that continues to operate in different landscapes in line with its grand strategy. Iran, North Korea and non-state actors are also major players in these conflicts.

Furthermore, it has been proved that grey zone conflicts will remain a primary tool for rival countries to help sustain conflicts below the threshold of war. They are also cheaper and less risky, so rival countries might pay a lower price compared with the catastrophic consequences of total war. Having said that, there is no certain explanation as to whether grey zone activities in cyberspace should be treated as state crimes, acts of war, interventions or violations of sovereignty. What is more problematic are the effects of these cyberattacks on the political realities/unrealities. Needless to say, these unrealities have become nonlocal hyperobjects that spread instantly anywhere in the world, regardless of the context. Even though it is not possible to see the immediate consequences of these conflicts in the cyber domain, it will be more challenging for countries unless global cooperation will be established through the regulations.

KEY TERMS AND DEFINITIONS

Cyber Sovereignty: This is a phrase commonly used in the field of internet governance to define the will of states to exercise and sustain control over the Internet domain within their own borders, including political, economic, cultural and technological activities. However, it is not clear how to apply this sovereignty concept to current international relations and international laws.

Cyberwarfare: Cyberwarfare is an overt or covert action of states, non-state actors or state-backed attackers that includes various tactics and techniques, notably advanced persistent threats, phishing tactics, viruses like Stuxnet, botnets, Trojan horses, zombies, Metasploit, SQL attacks, Rootkit, Nessus, pharming, Wireshark and buffer overflows to target infrastructure, software systems, and governmental institutions of different parties.

Grey Zone Threats: These are the threats that comprise a full spectrum of means and tools used by aggressor states to subvert their rivals' plans and strategies. These kinds of threats are perceived as affordable, less risky and flexible by the aggressor states.

Information Operations: Information operations are the part of political warfare/grey zone conflicts that occur in an asymmetrical way via social and conventional media, state organisations and military means to weaken the morale and psychology of enemy states.

The Law of Armed Conflict: The Law of Armed Conflict (LOAC), also known as the International Humanitarian Law, is a body of international law which regulates the behaviours of actors during armed conflict by ordering balance between military necessity and humanity. It comprises the Geneva Conventions, Hague Conventions and customary laws. It also limits the targeted attacks of combating parties in order to protect civilians and avoid total disaster.

Object-Oriented Ontology: Object-oriented ontology (OOO) is a school of thought which argues that objects exist independently of human understanding and perception. The term was coined by the philosopher Graham Harman. It is also designated in the existing literature as ‘speculative realism’, which criticises the reductionism of Kantian philosophy.

Ontological Approach to Cyberspace: It basically assesses cyberspace as a metaphysical laboratory that combines art and philosophy of things, machines and different domains, although this philosophical approach is not new.

Developing Cyber Buffer Zones

INTRODUCTION

Cyberspace has become the latest domain of war (Robinson, Jones, & Janicke, 2015), where modern international actors aggressively pursue their national security and foreign policy goals (Martins, 2018). Much research has been focused upon this area, covering topics such as the ethics of cyberwarfare (Dipert, 2010), legal aspects (Baradaran & Habibi, 2017), how best to conduct military operations inside of cyberspace (Liles, Rogers, Dietz, & Larson, 2012) and how to organise and defend nations from cyber attack (Ruiz, 2017) (THIBER (The Cybersecurity Think Tank), 2013). Surveys of the literature show a vast range of additional topics, demonstrating that research interest into cyber warfare is lively and diverse (Robinson, Jones, & Janicke, 2015). Whilst it is clear that interest in cyber warfare is high, there has been less attention paid to its aftermath. What effects on societies persist after cyber warfare and do these effects stymie work to restore peace and security to conflict torn regions?

The field of cyber peacekeeping addresses these questions, looking at conflicts which contain cyber warfare through the lens of peacekeeping. In this chapter, we provide a background to cyber peacekeeping and survey existing literature. We then make a contribution to the field by developing the concept of a cyber buffer zone.

BACKGROUND

The concept of cyber peacekeeping can be traced back to an article by Cahill, Rozinov and Mule (2003). They noted that cyber warfare would likely have devastating effects well beyond the boundaries of the combatants and that some kind of peacekeeping capability in cyberspace would be needed (Cahill, Rozinov, & Mule, 2003). Some potential cyber peacekeeping activities were proposed, such as cyber

DOI: 10.4018/978-1-5225-9715-5.ch019

border management and monitoring/verification and their overall approach was to explore how existing peacekeeping doctrine could be mapped to cyber warfare. The topic did not receive any further attention for ten years until Kleffner and Dinniss (2013) reignited discussion. They drew attention to the convergence of two significant global trends: an increase in conflicts which involve a cyber component and the increasing deployment of complex peace operations. They noted that these trends made it natural to assume that peacekeepers will find themselves asked to keep the peace in environments where the peace is threatened by cyber incidents (Kleffner & Dinniss, 2013).

Akatyev and James (2015) contributed by proposing a cyber peacekeeping model, including a set of goals and proposals of activities to perform during three stages: no conflict, conflict and post-conflict. In the no conflict stage, cyber peacekeepers work to unite efforts to keep the peace and prevent the outbreak of cyber conflict. In the conflict stage efforts are directed to orchestrating an international response and containing the harmful effects (e.g. through preventing the spread of malware or cyber weapons). Finally in the post-conflict stage, they propose that cyber peacekeepers are tasked with preventing further destruction and recovering critical infrastructure back to operation. In this regard, the model covers all three phases of warfare with the primary goal of protecting civilians.

The need for cyber peacekeeping was reinforced two years later by Dorn (2017), who states that cyberpeacekeepers could patrol and act in cyberspace just as current UN peacekeepers patrol and act in the world's conflict zones. Faced with a huge disaster bill and a potential for vast escalation in attacks, an investment in cyberpeacekeeping would seem like a bargain (Dorn, 2017).

In 2018, Robinson et al. (2018) built upon the foundations set by Cahill, Rozinov and Mule back in 2003. They reinforced the need for cyber peacekeeping with specific cases where cyber warfare would present a threat to international peace and security as defined by the United Nations. They explored how the activities of a modern multi-dimensional peacekeeping operation could be translated into a cyber warfare context, and evaluated each one according to two core criteria: value and feasibility. Any activity performed during cyber peacekeeping must bring clear value towards restoring peace and security, and must also be feasible to perform. They conclude that many of the existing UN peacekeeping activities would bring value in a cyber warfare context, but that feasibility can vary due to technical and political constraints.

Whilst such research into cyber peacekeeping is gaining momentum, further work is needed to develop the proposed activities and ideas into something practical: actions that could be concretely performed by peacekeepers in a cyber context to tangibly promote peace. The aim of this article is to contribute towards this goal by focusing on the concept of buffer zones.

FOCUS OF THE ARTICLE

In this article, we build upon the work of Robinson et al. (2018) by taking a closer examination of just one of the proposed activities: cyber buffer zones. The aim is to propose how the traditional peacekeeping activity of creating and running a buffer zone could be translated into cyber terms. To achieve this goal, we begin with a brief background of traditional buffer zones as used by UN peacekeeping. We then propose how the concepts behind a buffer zone could be translated into cyber terms, with emphasis on practical feasibility and ensuring that any proposal brings value towards peace. Data for this translation comes from both the cyber security and peacekeeping domains.

For this work, we adopt the methodology of Design Science Research (DSR) (Vaishnavi & Kuechler, 2015). The DSR approach is a set of synthetic and analytical techniques and perspectives (complementing positivist, interpretive, and critical perspectives) for performing research. The approach is directed toward understanding and improving the search among potential components in order to construct an artifact that is intended to solve a problem (Baskerville, 2008). It encourages problem solving through an approach of innovative solution design, where the focus of the work is upon contributing interesting, new and true knowledge through novel designs. In a new field such as cyber peacekeeping, where there is little existing knowledge, the DSR methodology is an ideal approach. The first stage of the DSR process is an awareness of the problem.

AWARENESS OF THE PROBLEM

Authors such as Robinson et al. (2018) and Akatyev and James (2015) have made a number of proposals on how cyber peacekeeping could be designed so that it can assist in maintaining peace and security in the face of cyber warfare. However, many of these proposals lack practical investigation. In this article, we therefore leverage the DSR process to pick out and design just one of these proposals: cyber buffer zones.

Interposition as a buffer zone is one of the core activities of a traditional UN peacekeeping operation. The UN defines a buffer zone as “an area established between belligerents and civilians that is protected and monitored by battalion peacekeeping forces and where disputing or belligerent forces and attacks on each other and the civilian population have been excluded” (United Nations, 2012, p. 92). Peacekeepers keep this buffer zone free from military personnel, weapons, installations and activities and have the authority to use force in order to protect the safety and integrity of the buffer zone (United Nations, 2012).

Robinson et al. (2018, p. 78) adapted this definition to produce a definition of a cyber buffer zone: “A network or site that is protected and monitored by peacekeeping forces, where cyber attacks have been excluded.” They proposed that a cyber buffer zone would be most valuable at sites where the greatest threats to peace exist, and an example of critical national infrastructure was given. These are sites that civilians rely upon for essential services such as electricity, water and transport. A cyber buffer zone could be deployed reactively (i.e. after a suspected attack) or proactively (preventive deployment in anticipation of an attack). The literature regarding buffer zones was distilled down to two core pieces of value which need to be preserved when designing cyber buffer zones:

1. **Deterrence:** Potential attackers are deterred from initiating an attack, due to the high probability of being detected and intercepted (increased chance of failure).
2. **Robust Force Projection:** When deterrence fails, the consequences for an attacker are significant e.g. incarceration, injury or death (increased consequence of failure).

It was suggested that deterrence in a cyber buffer zone can feasibly be achieved in a number of ways. Raising awareness that a particular site is under peacekeeping protection, knowledge that the site will be monitored by highly capable staff, and the increased likelihood of tracing attacks back to their origin could all have the potential to act as a deterrent.

With regards to projecting robust force, an approach which uses both short and long term activities was recommended. Further development of these activities was cited as future work, and this is where this chapter places its focus: proposing how such a cyber buffer zone would technically operate in order to achieve robust force projection and ultimately contribute towards maintaining peace.

SOLUTIONS AND RECOMMENDATIONS

To begin, it is prudent to first become familiar with the activities of a traditional physical buffer zone. The UN has been operating buffer zones for many decades, and this experience provides us with a solid foundation from which to consider cyber buffer zones. The activities they perform in a physical buffer zone have been refined and improved over the years, based upon field experience. We therefore can assume that any activity performed at a UN buffer zone is proven to have value towards restoring peace and is feasible in at least some cases.

The UN Infantry Battalion Manual Volume II (United Nations, 2012) provides a list of the specific tasks that peacekeepers running a buffer zone perform, along with a description of what each task involves. These are presented in Table 1.

Looking at Table 1 we can see that the value a buffer zone brings goes beyond just deterrence and robust force projection. It in fact serves to support multiple other peacekeeping activities ranging from humanitarian assistance to peacemaking. This emphasises the view that the activities of peacekeeping are synergistic: no one activity in itself can restore peace, but together they all work towards a common goal. When designing a cyber buffer zone, opportunities for synergy with the wider peacekeeping operation must be highlighted and encouraged.

An initial practical step in considering the design of cyber buffer zones is to determine if these existing activities could map to a cyber warfare context in a way that would be valuable towards restoring peace. This is our first contribution to knowledge: we take the same table and colour each activity: green if the activity holds potential value in cyber warfare, red if not. The description box is used to show our justification.

Studying Table 2, many of the existing buffer zone activities have potential to bring value as part of a cyber buffer zone. But this is only one piece of the puzzle: it shows there is value to be found but not how to feasibly achieve that value. The second piece of the cyber buffer zone puzzle is how to implement the cyber buffer zone and realise that value in a feasible way.

Looking to the field of cyber security, the concept of securing some infrastructure in the face of cyber attacks is not new. The domain of cyber incident response is a well-established field which can serve as a foundation for implementing a cyber buffer zone. The NIST computer security incident handling guide (Paul Cichonski, 2012) sets out four main tasks of incident response:

- Preparation
- Detection and analysis
- Containment eradication and recovery
- Post incident activity

These guidelines provide a good foundation but do not necessarily apply well to critical infrastructure (Ying, Maglaras, Janicke, & Jones, 2015) or indeed to a cyber buffer zone. For example, in regards to preparation it is suggested that network diagrams and lists of critical assets be created and stored. In the context of a reactive cyber buffer zone, peacekeepers may not have time to collect and study such documents. However, other parts are useful. For example we are reminded that a forensic capability is not only important for later legal proceedings, but also in the immediate concern of providing insight into the current state of the system (Eden, et al., 2016).

Table 1. UN buffer zone activities

TASK	DESCRIPTION
Tactical Deployment	Deploy tactical sub-units and detachments (both permanent and temporary) to effectively cover the entire frontage.
Monitoring	Observe, monitor, supervise and verify the cessation of hostilities/ceasefire/Truce/armistice agreements, compliance of agreements, troop deployments, etc.
Interposition	Interpose between opposing forces to stabilize the situation, where formal peace agreements are not in force.
Supervision	Supervise the implementation of the disengagement agreement.
Repositioning of Belligerent Forces	Accompany and support opposing forces to redeploy/withdraw to agreed dispositions and subsequent adherence to military status quo.
Control of BZ	Ensure no presence of military personnel, weapons, installations and activities, assist in securing the respective areas/line to prevent/intervene entry/intrusion without consent of military personnel, arms or related material in the Buffer Zone.
Civilian Activities	Monitor Crossing/Control Points across buffer zone for safe and orderly passage through by civilians in conjunction with opposing forces. Facilitate daily subsistence and routine activities of civilians in the buffer zone.
Contain	Prevent/contain violations/cross border attacks/isolated incidents taking place and if taken place, prevent it from escalating in to major conflicts.
Investigations	Follow up on complaints by investigations
Proactive Deployment	Proactive troop deployment to prevent an incident or its recurrence
Area of Limitations	Visit, monitor and ascertain compliance of activities periodically in stipulated "Areas of Limitations" (where military restrictions on deployment of body of troops and weapons systems and massing of troops not permitted).
Interface and Coordination	Act as go-betweens for the hostile parties with good liaison, close contact and effective coordination.
Assist Establishment of Local Authority	Assist/coordinate with local Government/belligerent parties in restoring its effective authority in respective areas
Assist in Good Governance	Facilitate good governance in the area of separation/bufferzone, contribute to maintenance and restoration of law and order and policing, establish interface with the inhabitants and help resumption of routine civilian activity (farming, electricity, water, medical support)for establishing normalcy.
Assist other entities	Assist/support formed military police elements, formed UN police elements/UNPOL, UN agencies in the area and other international organizations when tasked.
Mine Awareness	Support mine awareness, identify and mark minefields, and help in clearance of mines and unexploded ordnance.
Facilitate Humanitarian Access	Extend assistance to help ensure humanitarian access to civilian populations, provision of medical aid and facilitate voluntary and safe return of displaced personnel
Reconciliation and Rapprochement	Play an active and constructive role which is critical in preventing a recurrence of hostilities/ to prevent flash point, detrimental to the peace process and work towards a comprehensive political solution.
Assist Negotiation and Mediation	Assist UN mediator and undertake mediation and negotiation when tasked or required.
Other Activities	Facilitate exchange of prisoners, refugees, IDPs, dead bodies and to retrieve livestock.

The US based ICS-CERT(United States Homeland Security, 2009) provides guidance which is more tailored towards industrial control systems and much of the guidance provided can be adapted to help design cyber buffer zones. For example, it describes a number of staffing roles that are necessary including

Table 2. Existing buffer zone activities mapped to cyberspace

TASK	DESCRIPTION FOR CYBER BUFFER ZONE
Tactical Deployment	Deployment of cyber peacekeeping resources to effectively cover the network/site. E.g. experts, monitoring tools.
Monitoring	Use of cyber peacekeeping resources (examples above) to monitor cyber related ceasefire terms.
Interposition	Defend the network from cyber attacks: perform active cyber defence
Supervision	Dependent upon disengagement agreement. But some potential in a cyber context e.g. neutral observation of collaborative efforts to restore control of network to rightful owner or collaboratively remove malware as part of a political agreement.
Repositioning of Belligerent Forces	Cyber troops are difficult to observe and can attack from anywhere. Attempting to monitor or guide their repositioning would not be valuable in a cyber context
Control of BZ	Ensure no presence of cyber attacks and malware. Regular scanning of the infrastructure to ensure it remains clean and free of malicious activity/content.
Civilian Activities	Monitor cyber infrastructure for safe and orderly use by civilians for peaceful purposes. Some infrastructure will be used by civilians for peaceful and essential services. Peacekeepers can ensure the system remains available use e.g. banking, commerce, and government services.
Contain	Prevent or contain cyber attacks from impacting the infrastructure. Isolating and neutralising cyber attacks to avoid escalation into further conflict or relapse into warfare.
Investigations	Follow up on complaints of cyber attack/malware infections (cyber forensic capability)
Proactive Deployment	Proactive deployment of cyber defences to pre-empt and thwart potential attacks
Area of Limitations	Spot checks of networks to ensure that they are not compromised. This could relate to networks that do not have a full time cyber peacekeeping presence but should still be occasionally checked for compromise
Interface and Coordination	Cyber Peacekeepers in a cyber buffer zone can act as go-betweens for the hostile parties
Assist Establishment of Local Authority	Assisting the rightful owner of the network in regaining control e.g. restoring power grid and ensuring no unauthorised access remains
Assist in Good Governance	Advise network owner on how to best protect the network and potentially go beyond security to provide performance/optimisation advice. Long term cyber security capacity building.
Assist other entities	Assist police and other entities e.g. assisting with trace backs, providing cyber forensic capability in case of cybercrime.
Mine Awareness	Identify and contain malware, assist in malware clearance in the network and report on possible malware outside of infrastructure (e.g. detection of external botnet for other teams to follow up on)
Facilitate Humanitarian Access	Potential to protect hospitals from cyber attack, keep routes open (e.g. airport systems, air traffic control) and ensure basic services such as power and water to help humanitarian efforts succeed.
Reconciliation and Rapprochement	Cyber peacekeepers in a cyber buffer zone are unlikely to perform reconciliation duties
Assist Negotiation and Mediation	Some potential to assist wider negotiations through detailed knowledge of the network. E.g. How exposed it is, current events, when can the cyber buffer zone be withdrawn etc.
Other Activities	N/A to cyber peacekeeping

control system engineers, network specialists, system administrators, legal experts and vendor support specialists. This highlights how peacekeepers running a cyber buffer zone must bring expertise from a range of domains to protect the site. However, while we can use this guidance it is also not specific to a peacekeeping environment where one of the primary goals is the protection of civilians (UN Department of Peacekeeping Operations, 2015). Our second contribution is therefore to propose a set of activities for a cyber buffer zone, built using existing guidance where it makes sense but with new proposals where necessary, to suit the goals and conditions of peacekeeping.

We propose that peacekeepers at a cyber buffer zone could conduct three sets of activities following its establishment:

- **Phase One:** Immediate activities
- **Phase Two:** Longer term activities
- **Phase Three:** Withdrawal

PHASE ONE

Phase one consists of the immediate activities. These are rapid and decisive actions designed to gain situational awareness, stabilise the site, address any critical conditions which are an immediate threat to peace and security and restore essential services.

The phase begins by leveraging an existing concept from peacekeeping: a technical assessment mission (TAM) (United Nations Department of Peacekeeping Operations, 2014). In a proactive deployment, this will be a small team of experts who visit the site and assess its suitability for a cyber buffer zone. Since it is a proactive deployment, time will be available to become familiar with the site, collect network maps, asset lists, note observed problems and estimate the expertise that will be required. This is in line with existing guidance relating to the preparation phase of cyber incident response. In a reactive deployment, less time for preparation is available. A rapid response team may be a suitable way to address this problem: a team of peacekeepers who are able to quickly enter a site and perform a rapid assessment. The outcome is to gain situational awareness of the infrastructure, the resources required to secure and stabilise it and a determination on if the site would be suitable for a cyber buffer zone. Some key questions the TAM must answer include:

- Does the peace operation have the required resources to effectively run a cyber buffer zone at this site?
- Would a cyber buffer zone at this site provide value to the wider peace operation (e.g. could failure of the site threaten civilians, lead to state collapse, hamper restoration of state authority...)

If the TAM concludes that the site would be suitable for a cyber buffer zone, a team is established consisting of the required expertise. The process for establishing this team and ways of working (e.g. creation of a war room and communication procedures) can follow best practices described in the ICS-CERT guidance (United States Homeland Security, 2009).

The maintenance of peace and security must remain the overarching priority for a cyber buffer zone. We therefore propose that after establishment, a cyber buffer zone will conduct the following immediate tasks:

Stabilisation –In reactive deployments, a site such as a power plant or water treatment plant may currently be under attack, remotely via a network or locally via malware or insider. An essential task will be to prevent the condition of the site deteriorating. By this we mean working to prevent additional damage which could lengthen the amount of downtime or present a physical threat (e.g. explosion or contamination of water supply). Both of these are critical to avoid, since they are direct threats to peace and security. In proactive deployments where no negative effects are yet observed, the site will already be in a stable condition. Stabilisation will involve the following subtasks:

1. **Situational Awareness:** Both in reactive and proactive deployments, peacekeepers will need to quickly gain situational awareness: an understanding of the infrastructure, its assets, interdependencies, protocols and people. Information collected by the TAM will be useful here as a foundation. Confirmation of what is working and what is failing. Triage of expertise to specific components of the infrastructure for further analysis on the cause of the failures e.g. malware, exploited vulnerability, hardware fault, human error, malicious insider. In the case of attack, the team must determine the attack vector used.
2. **Action Plan:** Once the cyber buffer zone team has gained awareness of the infrastructure, an understanding of where failures are and attack vectors used an action plan can be developed. This plan will aim to directly address the most critical obstacles towards the site being stabilised and assign resources to actions. For example, vendor support experts may be assigned to replace failed hardware whilst malware and forensics specialists work to identify and neutralise malware on engineering stations. Others will be assigned to close the specific vulnerabilities used in attacks. The action plan must be discussed and agreed with all stakeholders, including local staff. Note that tasks one and two will not always be linear: following the action plan the team reassess the site and modify the plan based on new information or a change in the environment.

Phase one can be considered successful when there are no remaining immediate threats to civilians, damage is not spreading, malware has been neutralised (e.g. contained, command and control cut) and actively exploited vulnerabilities have been closed. The team can then proceed to phase two: longer term activities.

PHASE TWO

The goals of this phase are to restore service and establish a long term security capability at the site.

1. **Restoration of Service:** Once a site has been stabilised the next goal is to restore operation and resume provision of the service. Again this will require input from a number of areas including local staff, vendors and experts from the industry in question.
2. **Active Defence:** Once service has been resumed, it will be necessary to monitor the infrastructure and defend against any new attacks. Peacekeepers will deploy cyber defences: IP address blocking, load balancing, reconfiguration and redirecting of denial of service traffic are all examples possible defences. Companies such as Google have expressed interest in assisting the mitigation of denial of service attacks for good causes such as election monitoring groups and human rights organisations (Google, 2016). Organisations such as this would make good partners for a cyber buffer zone and demonstrates how important technology partners could be in making cyber buffer zones effective.
3. **Vulnerability Assessment and Hardening:** With the site stabilised, the team can begin the process of identifying other weaknesses in the security of the infrastructure: known vulnerable or unnecessary software/services, misconfigurations, weak credentials, unnecessary external connections, weak policies, security blindspots, gaps in physical security or human resource security. These are vulnerabilities which threaten the ongoing security of the site, but were not actively being exploited in phase one. Due to the fragile nature of industrial control systems (Wedgbury & Jones, 2015),

vulnerabilities will not be closed until a plan is developed in collaboration with all stakeholders including local staff. The reason for this is twofold: first because patching software or changing long standing configurations may have unexpected consequences upon the operation of the site. Second, local stakeholders need to be engaged and involved in decision making to ensure ongoing cooperation and success of the buffer zone. The end result will be a hardened infrastructure, resilient to future attacks.

4. **Restoration of Control:** The immediate activities focused upon protecting civilians by tackling critical threats, not upon restoring all systems back to the control of the legitimate owner. In this regard, non-critical systems at the site might still be under attacker control even after phase one has completed. This activity aims to restore full control of all systems at the site back to the legitimate owner.
5. **Monitoring and Supervision:** With the immediate threats countered, cyber peacekeepers monitor the site and supervise collaborative efforts e.g. collaboration between two parties to remove malware, arranged as part of a peace agreement.
6. **Cyber Forensics:** Cyber peacekeepers can begin to provide forensics services to identify how breaches occurred and what information was stolen etc. This is useful for verifying ceasefire agreements and for third party enquiries such as national police.
7. **Peace Support:** Cyber peacekeepers can use their knowledge of the site and its staff to support wider peacekeeping tasks. For example they can provide evidence on compliance with cyber terms, report upon ongoing attacks from external sources, act as an intermediary between the hostile parties, support police investigations and share information on malware which may be valuable for other cyber buffer zones in a region.
8. **Training:** Local staff are trained in security best practices specific to the infrastructure they are maintaining, for example developing incident response plans relevant to industrial control systems. The goal is to build a local capability so that peacekeeping forces can proceed to phase three and withdraw from the site.

Phase two activities will continue until local staff are able to maintain the security of the infrastructure without cyber peacekeeper assistance. This goal is in line with existing peacekeeping doctrine, which strongly encourages local capacity building to enable eventual withdrawal of UN forces (United Nations, 2008).

PHASE THREE

Withdrawal: The eventual goal of peacekeepers, in all domains, is to build a local security capability and hand over responsibility for security to local staff. A cyber buffer zone will be no different: peacekeepers cannot stay at the site forever, and must eventually withdraw once a local capability has been built. This local capability should be effective enough to ensure the site is well protected in the long term. Activities in phase two are designed to contribute towards this: hardening of the site and training are both activities which aim to enable eventual withdrawal of cyber peacekeeping services.

A visual representation of the three phases, along with how each activity maps to the existing activities of a physical buffer zone is presented in Figure 1.

Figure 1. The three phases of a cyber buffer zone (own synthesis)

CONCEPT EVALUATION - FUTURE RESEARCH DIRECTIONS

The proposals made in this article are crafted to fulfil the goals of a UN peace operation (namely, to protect civilians) whilst remaining feasible to perform. In this section, we discuss where obstacles may arise and avenues for future research.

Local Resistance

The success of a cyber buffer zone as described in this article is highly reliant upon the cooperation of local staff. Cyber peacekeepers will find it difficult to perform the activities we describe if local staff do not provide assistance, or actively resist. Cooperation of local staff should be measured by the technical assessment mission, and a lack of cooperation is grounds for denying a buffer zone. Unfortunately this could place the UN in a difficult situation. For example, in a case where critical infrastructure is failing to the point where it presents a threat to civilians yet local cooperation is lacking. This is a challenging scenario where future research would be welcomed.

Lack of Consent

While local resistance represents an unwillingness to cooperate at the field level, we must also consider a lack of consent at higher levels. Consent of the parties is one of the core principles of UN peacekeeping (United Nations, 2008), and is required for the success of the operation. Take a scenario where critical infrastructure is failing and threatening civilian security, and local staff appear to be unsuccessful in tackling the threat. The UN may feel that a cyber buffer zone is critical for peace and security in the region but may find that consent is not given by the host nation. Following existing doctrine, this naturally leads to the question of peace enforcement.

Peace enforcement has been used in the past for the following purposes (Bellamy & Williams, 2010):

- To restore or maintain international peace and security.
- To enforce sanctions.
- To defend peacekeeping personnel.
- To provide physical protection to civilians.
- To protect humanitarian activities.
- To intervene in internal conflicts.

It is therefore not radical to propose that the UN has the option to forcefully impose a cyber buffer zone at CNI which threatens the physical security of civilians or the maintenance of international peace and security. The importance of the UN's authority to enforce peace was supported by ex-secretary general Boutros-Ghali who stated that "while such action should only be taken when all peaceful means have failed, the option of taking it is essential to the credibility of the United Nations as a guarantor of international security" (United Nations, 1992, p. 12). If it is agreed that the authority to enforce a cyber buffer zone exists, it must be asked if it would be feasible. This would be a valuable area for future work.

Ensuring Impartiality

Impartiality is the second core principle of UN peacekeeping, and must be upheld when establishing cyber buffer zones. Ensuring that a buffer zone is impartial, and is seen as such, may become a challenging task. This is because cyber peacekeepers are taking an active role: bolstering defences, training staff and restoring control. Care must be taken to ensure that any buffer zone has the clear, publicised aim of protecting civilians. It is necessary to emphasise that they will only be established at sites where a lack of protection could endanger the human rights of civilians. Military sites and systems will not be protected. It must also be made clear that a buffer zone is focused upon defence, and not offence.

A potential threat to the appearance of impartiality is that establishing a UN cyber buffer zone to protect CNI frees up that nation's cyber troops to focus upon offence rather than defence. This has the potential to lead to undesirable incentives such as letting CNI fail or purposely creating incidents so that the UN will step in and provide protection. This is a valid concern that must be considered. One response is to only provide a buffer zone once peace has been agreed. If a nation then wishes to cheat and continue offensive cyber operations while enjoying the benefits of the buffer zone, this is a risk that could result in consequences on the international stage.

The problem of resource hoarding also exists. Country A may request many cyber buffer zones simply to consume UN cyber resources and deny the service to its rival. Cyber peacekeeping resources must therefore be provisioned in a balanced manner, with restraint in mind. The technical assessment missions will be crucial here, to decline requests where there is no clear need. The protection of civilians will always be the greatest deciding factor regarding where cyber buffer zones are established.

Securing Critical National Infrastructure

It has been argued that cyber buffer zones will likely bring most value when established at a critical national infrastructure (CNI). It is a known issue that the hardware, software and protocols which operate CNI are particularly challenging to secure from a cyber perspective. Firstly they make attractive targets to a wide spectrum of attackers. Nation states, terrorist groups, hackers, activists, organised crime and disgruntled insiders all potentially have an interest in attacking CNI (Robinson, 2013). Secondly, the technology used at such sites is known to possess characteristics which make it particularly vulnerable to cyber attack and challenging to defend (Merabti, Kennedy, & Hurst, 2011). A discussion into all of the security issues of CNI is beyond the scope of this paper, but extensive literature exists in this area (Robinson, 2013) (Gao, et al., 2014) (Nicholson, Webber, Dyer, Patel, & Janicke, 2012). Instead, we will highlight challenges that present a specific problem to a cyber buffer zone.

Arguably one of the major challenges peacekeepers will face in building a cyber buffer zone will be to work with the hardware, software and protocols. These components can be decades old, built using proprietary technologies, fragile in their operation and designed/tested in an isolated environment. These characteristics will make establishing a cyber buffer zone at CNI much more challenging than in a traditional ICT environment.

To give a concrete example, let us consider phase one. During this phase, the peacekeepers aim to stabilise the infrastructure by identifying where critical negative effects are originating from and resolving the issue. At a traditional ICT based environment, this would involve the use of various monitoring tools. The NIST guidance suggests the use of network and host-based IDPSs, antivirus software and log analysers (Paul Cichonski, 2012). Research suggests that using such tools at CNI could have negative effects on the functioning of core components, causing them to become unresponsive, slow or unpredictable in behaviour (Coffey, Smith, Maglaras, & Janicke, 2018). It is also rare for such components to hold any logs or other forensic artefacts of value which can be retrieved (Eden, et al., 2016). Even the act of closing a vulnerability through patching firmware, software or making a configuration change could be enough to cause unexpected results which worsens the situation. The conclusion we must reach is that peacekeepers entering CNI to establish a buffer zone will require very specific skillsets in order to correctly diagnose and remediate cyber incidents without making the incident worse.

Gaining Situational Awareness

In the case of a reactive cyber buffer zone, peacekeepers may be asked to deploy with no or limited pre-existing knowledge of the site's hardware, software and protocols. This makes gaining situational awareness of the infrastructure an important task but difficult task. The age of the components at the site make it possible that the vendor who produced them is no longer in business. This immediately presents an obstacle towards finding expertise, documentation and replacement parts. Network diagrams may be missing or inaccurate. In the context of a warfare environment, local staff who could share knowledge may be absent. A site suffering negative effects which are directly harming civilians (e.g. faulty water treatment) will also place pressure upon the team to act quickly. Work which explores how a cyber buffer zone team can quickly gain knowledge and situational awareness of critical infrastructure under these conditions would therefore be valuable.

Difficulty to Train

Peacekeepers working on other activities can perform training to prepare themselves for deployment in the field. For example, exercises can be run to simulate a physical buffer zone and the types of scenarios they could face. Simulating a cyber buffer zone for training purposes will be more challenging. Due to the problem of fragility at CNI and a 100% uptime requirement, the UN will have difficulty finding a site where cyber peacekeepers can test their tools and processes. Simulations are a possible solution here, but producing such a simulation, which could accurately model cyber warfare's effects on critical national infrastructure and its components is a complex task. Efforts in this area do exist (Ferreira, Machado, Costa, & Rezende, 2015) but further research would bring value to developing effective cyber buffer zones.

Securing Cyber Expertise

Cyber security expertise is in high demand across the world, with some estimating that by 2021 there will be 3.5 million unfilled cyber security roles across the public and private sector (Morgan, 2017). With threats in cyber space only rising, the demands for staff with cyber expertise will only continue to grow. This presents a challenge to the concept of cyber peacekeeping: where is the expertise going to come from and how will it be funded? Peacekeeping organisations such as the UN rely upon contributions of troops from member states, but it is questionable if states already short on cyber expertise would be willing to lose them to support a peace operation. We have also proposed that a cyber buffer will need a range of skillsets, including some which come from the private sector. It must therefore be asked what incentives these private organisations would need to contribute their expertise. Research on why states contribute towards peace operations is well established (Bove & Elia, 2011) (Bellamy & Williams, 2013), and it would be useful to explore how this body of work can be applied to the concept of cyber buffer zones.

Political, Legal and Social Concerns

The concept of peacekeeping is one which touches upon multiple domains of thought. Legal, social, political and military considerations all come together to make peacekeeping a success. A cyber buffer zone will be no different. Studies which examine the legal implications and requirements will be es-

sential. For example, it is likely that many sites critical to the protection of civilians will be owned by private entities and not the nation state itself. This raises questions about a state's ability to consent to a buffer at sites it does not outright own. Questions of privacy, data protection and ethics may also arise in the case of peacekeepers of multiple nationalities entering infrastructure to perform monitoring of network traffic. On the political aspect, highly cyber developed nations may be wary of sending their cyber experts to work alongside those from rival nations. There is even the possibility for cases where a nation is conducting or condoning cyber attacks on one hand, whilst contributing cyber peacekeepers with the other. In this regard there is potential for the goals of a cyber buffer zone to become subverted for ulterior motives, or at least for the suspicion of such to exist between nations. Research which explores and resolves these aspects is valuable towards making cyber buffer zones a success.

CONCLUSION

UN Peacekeeping has been operating since 1948, working to maintain peace and protect civilians around the world, and buffer zones in particular have featured throughout the history of UN peacekeeping as a means to physically separate conflicting forces, protect civilians and ensure peace in a region. As war increasingly gains a cyber component, it is important to consider how peacekeeping must adapt to remain effective. The field of cyber peacekeeping addresses this issue, and in this chapter we have made a contribution by proposing a possible design of a cyber buffer zone, based upon a three phase approach. This approach was built by fusing together knowledge from both the cyber security and peacekeeping domains.

We critically evaluated our design against two core criteria: that it should be feasible to perform and provide some kind of tangible benefit to peace. From the perspective of value, a cyber buffer zone can directly address one of the main goals of UN Peacekeeping: protection of civilians. As societies become increasingly reliant upon cyber space for the provision of services such as power, water, finance, transport and commerce, the impact that cyber warfare could have upon these services rises. Failure of a smart grid, air traffic control or the rail network could at the very least prevent a nation and its citizens from recovering to a level where peace can be maintained. In some cases, it could lead to loss of life.

We have therefore designed cyber buffer zones as an activity which consists of both immediate and longer term activities. The focus of the immediate activities is to rapidly address any pressing threats to civilians and peace. Once this has been achieved, cyber security at the site is bolstered so that it remains resilient into the future.

While a cyber buffer zone is valuable, we have shown that there are many challenges to overcome in relation to feasibility. Critical national infrastructure can be difficult to secure, especially at short notice without much prior knowledge of the hardware, software and protocols in use. It will also require specific expertise that will likely be expensive in a market where cyber expertise is in high demand. Our solution proposal to the problem of developing cyber buffer zones is therefore not perfect: it requires further work and input from the research community, and for alternative designs which can overcome or reduce these obstacles. In this regard, it is hoped that this work can serve as a discussion point from which further progress can be made.

INTRODUCTION

Within the last two decades, corporate scandals, fraud and corruption, unethical and illegal business practices, misconduct in the workplace, malpractice, and the mismanagement of funds have all been associated with corporate wrongdoing in the public and private sectors. Indeed, such a business context has arguably led to disgruntled employees, poor company images, and many publicized corporate melt-downs within powerhouse corporations across the globe. The effect of corporate failures brought devastating effects to the global economy as triggers to the economic recession in 2008. Undeniably, therefore, corporate wrongdoing must be brought under control within today's workplace for all organizations.

Effective control of corporate wrongdoing within today's workplace calls for clear, structured, accepted, and well-managed procedures to facilitate whistleblowing. A managerial perspective must therefore, be adopted to systematically establish and support whistleblowing. In the corporate context, whistleblowing can be defined as a disclosure process which uses various channels (internal and/or external) for organizational members (past or present) to report illegal, immoral or illegitimate practices within an organization, with the aim of stopping or addressing the harm or threat (Near and Miceli 1985). Immoral practices also cover wrongful and questionable commissions and omissions on the part of the organization to protect their members from serious harm (Near and Miceli 1996). In this regard, whistleblowing can assist in rooting out corruption and wrongdoing by bringing such issues to the forefront. Whistle-blowers should therefore, be seen as heroes since they can assist in saving billions of dollars and numerous lives through the disclosure of information regarding fraud, corruption, and other forms of corporate wrongdoing and misconduct by organizations, thereby protecting citizens, employees and consumers, and preventing related disasters and scandals from intensifying.

Despite the potential of whistleblowing as a process for managing corporate wrongdoing, its effectiveness has often been brought into question by opponents due to several reasons. First, the decision to report the observed wrongdoing is never an easy one, given the high personal costs, which can deter whistleblowing. In some contexts, whistle-blowers can be regarded as heroes, while in others, they can be perceived as traitors and snitches. Second, organizational leaders and management can respond in a number of different ways, which may or may not be favourable to the reporter or whistle-blower. Managerial responses can include: correcting the wrongdoing, ignoring the report, or even retaliating against the whistle-blower. Positive managerial responses can signal to employees that management accepts the whistleblowing behaviour in the organization and is prepared to curb the wrongdoing. Negative managerial responses in the form of victimization and/or no action can serve as a disincentive to

whistleblowing. In such a context, it is apparent that the effectiveness of whistleblowing in addressing corporate wrongdoing can be limited. To maximize the potential of whistleblowing, therefore, it becomes important to answer the question: “How can organizations manage whistleblowing to effectively address corporate wrongdoing in today’s business environment”? To answer this question, the research objectives of this Chapter are to:

- Describe the key management issues associated with whistleblowing.
- Outline the essential aspects of the ethical dilemma in the management of whistleblowing.
- Present and evaluate a managerial framework to enhance the effectiveness of whistleblowing.

BACKGROUND

Recent failures of corporate integrity among high-profile organizations have emphasized the need to prevent, detect, and respond to corporate wrongdoing that can lead to devastating consequences for economies, businesses, employees, and other stakeholders. Whistleblowing in today’s corporate world is increasingly becoming a mainstream issue, since it is the key component in promoting a culture of integrity. Whistleblowing generally describes the process through which corporate wrongdoing can be exposed; where exposure should set the stage for managing and minimizing such wrongdoings. The range of activities that may constitute corporate wrongdoing include, but are not limited to: corruption, bribery, receiving and giving gifts and entertainment, kickbacks, extortion, nepotism, favouritism, cronyism, money laundering, improper use of insider information, insider trading, conflicts of interest, fraud, discrimination, aggressive accounting, sexual harassment, workplace safety, product safety, and environmental pollution (Near and Miceli 1996). All definitions of whistleblowing establish that it involves the reporting of such wrongdoing, that wrongdoing is not confined to illegality, whistleblowing is not confined to reporting to fellow employees, and whistleblowing should encourage persons to report activities that may be fraudulent or harmful to the business and stakeholders (Near and Miceli 1996).

Notably, whistleblowing can be done via internal and external channels. If an alleged wrongdoing is reported to internal authorities, such as, persons in positions of authority within an organization, audit committees, or anonymous channels, it is referred to as internal whistleblowing. If an alleged wrongdoing is reported to outside authorities, such as, regulatory bodies, news media, or public interest groups, it is referred to as external whistleblowing. There is some consensus that whistle-blowers may prefer to blow the whistle through available internal channels. However, most employees may be too scared to blow the whistle internally for fear of victimization, retaliation, reprisal or even dismissal. Fletcher, Sorrell, and Silva (1998) in their research on whistleblowing note an important case study which highlights clearly some of the issues that could emerge using even internal whistleblowing channels.

In 1996, in a New England hospital, a registered nurse Barry Adams blew the whistle using internal channels on unsafe health care practices he observed in his workplace. He documented the unsafe practices and noted instances where patient safety, healthcare and well-being were being compromised. For three months, such practices were documented and reported to internal hospital administrators using the prescribed processes and procedures. However, Adams soon realized there was little to no interest in correcting the unsafe practices, no interest in using the information to do so, and in fact, he was harshly

criticized for collecting such information. Adams subsequently took a different approach by refusing to participate in acts that were contrary to established legal and ethical practices, for example, he refused to take narcotics orders from a physician's technician, citing its contradiction with legislation such as the Nurse Practice Act. The response; Adams was threatened, and although he had a track record of excellent performance reviews, he was eventually fired. Adams took this matter to court and won his case; subsequent appeals by the hospital were turned down.

From the case, it is evident that even internal whistleblowing can have undesirable consequences for the whistle-blower, which may nullify benefits that could be derived from the disclosure of corporate wrongdoings. Many employees in today's corporate world, as well as, other organizational stakeholders may be hesitant to report any perceived corporate wrongdoing, since they can become stuck in what is referred to as the "whistle-blower's dilemma". Here, the reporter is faced with the predicament of weighing the positive impact of his impending revelation and the possible dangers to his life, family, reputation, and profession. Such reporters generally may not feel adequately protected to come forward with information on misconduct and corrupt practices. Where reports are made, as seen in the New England case, they can face retaliation, victimization, intimidation, recrimination by supervisors or co-workers, denial of work-related benefits, suspension from work, and at times, outright dismissal. These negative consequences can lead to low participation in the internal whistleblowing process as an avenue for the disclosure and management of corporate wrongdoing.

Fletcher, Sorrell and Silva (1998) further make a number of important points with the New England case study that while there may be problems with internal whistleblowing; such problems emerge largely due to the failure of organizations to follow and act on documented ethical guidelines/policies to safeguard the interest of all organizational stakeholders, and that external whistleblowing could only possibly be considered an option when there is a failure of internal organizational ethics. In fact, whistleblowing itself should not even occur if there are effective internal procedures to address staff concerns within an ethical organization. If the organizational ethics and internal procedures were effective at the New England hospital, the unsafe practices would not have been tolerated and Adams would not have unsuccessfully exhausted the internal channels of communication before taking legal recourse for his wrongful dismissal, following his whistleblowing.

When all is said and done, it is important that the whistle-blower blows the whistle for the morally right reason; preserving the safety and welfare of all concerned, and not for selfish personal gains. Registered Nurse, Barry Adams appeared to have the safety of the patients at heart in his disclosure in the 1996 whistleblowing case. From a deontological view, Adams's duty to the safety of patients supersedes his duty or loyalty to such an organization. Studies consistently show that whistle-blowers are motivated by moral reasons. The primacy of moral concerns makes sense, considering how frequently whistle-blowers face exclusion and retaliation rather than personal gain. For example, more recently, in May 2015, the Securities and Exchange Commission (SEC) punished Deutsche Bank with a \$55 million fine. Deutsche's crime was inflating the value of its portfolio of complex derivatives by \$1.5 billion during the financial crisis. The SEC promised former Deutsche Bank risk analyst, Eric Ben-Artzi, \$8.25 million for his role in exposing this overvaluation by providing documents to regulators. This payout resulted from the whistle-blower program introduced under the 2010 Dodd-Frank law, which rewarded eligible individuals who voluntarily provide information leading to successful sanctioning of over \$1 million. Depending on the case, whistleblowers could receive 10 to 30 percent of the sanctions collected. The

rationale behind this program was to motivate organizational members to come forward to expose corporate wrongdoing. Indeed, Ben-Artzi noted when he first began helping the SEC with their investigation the prospect of a financial reward was a “powerful incentive.” Except, stunningly, Ben-Artzi refused to accept his payout, explaining that he was willing to forego his multi-million dollar reward because the top executives responsible for Deutsche’s crime went completely unpunished and instead retired with multi-million dollar bonuses. Under the Dodd-Frank whistleblowing program, vindication is generally rare as well. As of last year, the SEC had awarded only 22 whistle-blowers despite receiving 14,116 tips since the whistle-blower program’s inception (Duncan, Waytz and Young 2015). Ben-Artzi’s case illustrates that the motivations of whistleblowers extend far beyond practical concerns and financial gains, and also sheds light on the limited functionality of the current U.S. whistle-blower program. It is therefore, apparent that ethical and legal conflicts can impact the effectiveness of whistleblowing to address corporate wrongdoing as well. The Deutsche case and the failure of prosecutors to punish the wrongdoers following the disclosure of Ben-Artzi demonstrate the need for stronger legislative frameworks to fully support the whistleblowing process and to address legal loopholes.

Whistleblowing indeed presents an ethical dilemma for observers of corporate wrongdoing and De George (1986) presents the key aspects of this ethical dilemma in three perspectives: whistleblowing as morally prohibited, morally permitted and morally required. The most common argument for not blowing the whistle is loyalty. However, loyalty or duty to one’s organization of employment or organization of interest as an argument against whistleblowing ignores the norms of a democratic society, the freedom of speech and the ethical notion that absolute loyalty to any entity or anyone does not exist in reality. Loyalty to one’s organization within one’s employment agreement does not ethically allow the observer to ignore practices and policies that could cause serious harm to others within or outside private and public organizations. Whistleblowing is in fact morally permitted under a number of conditions which permeate today’s workplace. For instance, if customers, innocent bystanders, or the general public may be seriously harmed in any way by an organization’s products, services, practices or policies, the disclosure of such wrongdoing should be permitted. In such a case, if one’s immediate supervisor is passive about the disclosure or complaint, the employee should then exhaust the internal procedures and possibilities within the organizational hierarchy to make his concern known (De George 1986). Whistleblowing then becomes absolutely required when the whistle-blower has access to documented evidence to convince an independent, reasonable, impartial observer that the company’s products, services, practices or policies poses a serious threat to customers, bystanders or the general public. Therefore, the probability that the wrongdoing would be managed, upon disclosure, must be worth the risk and danger being taken by the whistle-blower in exposing the threat or harm. Drawing from the case of wrongdoing at the New England hospital, it is clear that Barry Adams did no wrong as a whistle-blower, following documented internal procedures for disclosure, and whistleblowing was indeed absolutely required with documented evidence of unsafe health practices at the hospital. Even so, whistleblowing in this instance was unsuccessful in addressing the unethical and illegal practices identified. It is therefore, apparent that there is a need for a comprehensive management framework to maximize the power of whistleblowing to address corporate wrongdoing, while addressing the challenges that can negatively impact its effectiveness.

FOCUS OF THE ARTICLE

Management Framework for Whistleblowing

When developing a comprehensive managerial framework for whistleblowing, and to maximize its benefits to address corporate wrongdoing, the key aspects of the whistleblowing process must be clearly outlined, well-detailed, openly communicated, and widely accepted.

The Whistleblowing Process

From a managerial perspective, there are four key aspects to whistleblowing:

1. The identification that the act is wrongful and can cause harm
2. THE decision to report the wrongdoing
3. the organizational response to managing, addressing and ending the wrongful acts
4. The organizational response to the whistle-blower

Identification of Corporate Wrongdoing

Firstly, what constitutes corporate wrongdoing must be clearly articulated by private and public organizations. Organizations can no longer rely exclusively on internal codes of conduct and ethical structures to prevent all unethical behaviour, but have to depend to some degree on individuals who are willing to blow the whistle if they detect illegal, dangerous or unethical activities as well. Generally, corporate wrongdoing falls into the following categories: criminal offences, the failure to comply with obligations outlined by organizational policies and law, any miscarriage of justice, endangering of employees, stakeholder or public health and safety, damage to the environment, and the covering up or ignorance of wrongdoing in any of the aforementioned areas (Near and Miceli 1996). More recently, managers and researchers have articulated the need for more clarity in what specific acts constitute corporate wrongdoing, and hence, what acts can be exposed through whistleblowing channels and mechanisms. For example, corruption and fraud are more clearly identifiable as illegal acts. Unethical acts such as conflicts of interest however, may not be clearly identifiable as corporate wrongdoing, although such acts can also cause serious harm to organizational stakeholders and the general public. It is therefore, crucial that public and private organizations establish and publish a domain of acts, which pose a threat or harm to human safety and well-being.

Reporting of Corporate Wrongdoing

Putting measures in place to detect wrongdoing in organizations is important, but reporting to correct wrongdoing is also vital (Kaptein 2011). Employees who detect wrongdoing should, therefore, be encouraged to respond in a manner that supports corrective action. Whistleblowing is contrary to the tradition that an employee does not question a superior's decisions and acts, especially not in public. What is at stake is the employee's right to speak out in cases where they think the organization or management is

engaging in an unacceptable practice that could harm other employees, the welfare of the organization, innocent bystanders, the environment, and/or the public. If employees conclude that they cannot discuss or report current or potential unethical activities with co-workers or superiors, they may go outside the organization for assistance to address such wrongdoings. This is where decisions must be taken to report or not to report, to report internally or externally, or to leave the organization; decisions which are never easy for the observer.

The decision to stay silent and/or leave the organization both close the door to the benefits of whistleblowing as a mechanism for exposing and rooting out corporate wrongdoing. Further, reporting internally or externally both opens the door to maximize the benefits of whistleblowing, while also raising issues of protection for the observers. There has been some consensus among researchers that internal whistleblowing is preferred by most whistle-blowers and most organizations; a point acknowledged before. Internal whistleblowing gives the organization an opportunity to solve the problem behind closed doors and in internal way. In some cases, internal whistleblowing may even be perceived as the employee exhibiting loyalty and commitment to their organization. The success of internal whistleblowing, however, depends on its acceptance by the organization and its members, as well as, the organization's openness to and acceptance of disclosure.

According to Berry (2004), the ethical culture of organizations also plays a crucial role in stimulating employees to report wrongdoing internally, with the expectation that the practices can be corrected and the infractions can be addressed. Ray (2006) went on in her study to detail a case where all internal whistleblowing through the hierarchy of the organization failed, similar to the New England case of Barry Adams; however, external whistleblowing was used, because ethical standards were clearly contravened and organizational ethics failed. She argued that an organization that does not support those that whistleblow because of a violation of professional standards is indicative of a failure of organizational ethics. In that case, it was observed that a nurse told patients of schizophrenia within an acute care psychiatric facility that she could 'cure' their mental illness by the laying on of hands, which she proceeded to do both individually and in groups. She was not practicing therapeutic touch but physically touching the patients on various parts of their bodies without their consent. After these sessions the patients were visibly upset and required medication to help them to settle down. After reporting through the organizational hierarchy failed, the matter was reported externally to the Canadian Nurses Association and the College of Nurses of Ontario (CNO) for action, since the reported practices clearly contravened Codes of Ethics and Standards of Practice. When employees report organizational misconduct through external channels, it can create havoc within the company in the public domain. However, external whistleblowing becomes an option for whistle-blowers when the ethical culture of the organization largely fails to take corrective action through internal whistleblowing. It is therefore important for management frameworks to focus on building a strong ethical climate or a moral community within organizations as Ray (2006) states. Within a moral community, there is no gap between what employees know is the right thing to do and what they actually do. Developing a moral community means using strong values and ethical beliefs to guide organizational decision making and practices. A relational view may therefore be more effective within the management of whistleblowing by fostering an interdependent moral community to address ethical concerns.

Where infractions do occur however, anonymous whistleblowing may be preferred to whistleblowing where the reporter is identified. When employees reveal organizational wrongdoing using their real name (providing information that recognizes the individual employee personally), it is referred to as identified whistleblowing. Conversely, when employees report organizational wrongdoing by hiding their identity, it is referred to as anonymous whistleblowing. Empirical research (e.g. Kaplan and Schultz 2007;

Robinson, Robertson and Curtis 2012) suggest that when employees use anonymous whistleblowing, the reporting of organizational misconducts, such as, fraud and corruption increases since the perceived personal cost of blowing the whistle decreases for the whistle-blower. Anonymous reporting, therefore, enhances the effectiveness of whistleblowing to discern and expose corporate wrongdoing. However, while blowing the whistle anonymously tends to make the disclosure easier for the whistle-blower, it can create difficulties in the investigation of the report if the organization does not have designated procedures where confidentiality and anonymity are maintained as part of the organization's response to managing the report and putting an end to the reported wrongdoing.

Organizational Response to Managing, Addressing, and Ending Corporate Wrongdoing

The organization and its members need to share a firm conviction that the tolerance of illegal and unethical behaviour is not in their own, or the organization's interests, and that the eradication of corporate wrongdoing must become internalized. Organizations must therefore implement an effective internal system for employees to raise concerns and to facilitate the process of whistle-blowing internally. If individuals feel that it is not safe and accepted to blow the whistle internally, they will resolve to blow the whistle externally. Management must further demonstrate a commitment to investigate all allegations promptly and thoroughly, and report the origins and the results of the investigation to a higher authority. Too often, the reporting channels are not trusted, and observers of wrongdoing are uncertain of the organizational agent to make reports. Within both case studies in the healthcare industry, unfavourable organizational responses, or rather, no responses to observed and reported wrongdoing transpired subsequent to reporting.

It is apparent that within organizational responses to corporate wrongdoing, three parties are important: the individual(s) who commits the (alleged) wrongdoing, the observer who considers the act wrong and reports it, and the recipient of the whistle-blower's report. When developing and implementing whistleblowing policies all parties must be covered. The implementation of whistleblowing policies are increasingly being recommended by many codes of corporate governance as well. At a minimum, an effective internal policy on whistle-blowing should include: a clear statement that malpractices are taken seriously, confidentiality is respected, that there are penalties for false and malicious allegations, and a clear indication of how the concern can be raised internally and as a last resort, externally if necessary. The internal system should also include proper communication channels, commitment by management to the whistle-blowing process and support approaches for the whistle-blower. Since corporate governance is fundamental to effective management within an organization, this means whistleblowing policies can be part of internal auditors' responsibilities as well. In 2014, the Securities Exchange Commission (SEC) announced a whistle-blower award of more than \$300,000 to a company employee who performed audit and compliance functions. This employee reported wrongdoing to the SEC after the company failed to take action when the wrongdoing was reported it internally. Indeed, individuals who perform internal audit, compliance, and legal functions for companies are on the front lines in the battle against fraud and corruption. They often are privy to the very kinds of specific, timely, and credible information that can prevent an imminent fraud or stop an on-going one. Managerial frameworks on whistleblowing should therefore, incorporate the role of internal audits and audit committees. The use of financial rewards however, should be closely monitored to prevent possible abuse of the system for personal gains.

Organizational Response to Whistle-Blower

To blow the whistle is not an easy task, it needs courage, moral evaluation, and one has to put the interest of the public ahead of his or her interest. Despite this, many praise whistle-blowers for heroic and noble deeds; many also condemn them as malcontent, trouble makers and misfits for exposing misfeasance and wrongdoing of their colleagues and management. The whistle-blower can be viewed positively, or negatively, regardless of whether the whistle has been blown through internal channels or, as a last resort, through external channels. The response of the organization to the whistle-blower, whether positive or negative, largely depends upon the style and approach of top management.

Organizations need to create an environment where employees can feel safe as whistle-blowers and where they are encouraged to report wrongdoing knowing that they will be protected and that the wrongdoing will be addressed. In this regard, top management support largely shapes this environment and hence the organizational response to the whistle-blower. As organizational policy-makers, top managers must consider the whistle-blower objectively. It is not an issue that can be ignored, due to the possible negative consequences for the whistle-blower, other employees and the organization. Managers should therefore, be supportive of employees who may have a problem as an observer of corporate wrongdoing right through to the management of the issue and the organizational life of the whistle-blower after the issue is addressed.

Like most initiatives, a whistle-blower program is most effective when supported by the organization's leadership. If the company has cohesive whistle-blower and ethics policies – and if both are adhered to by management – then individuals will be more willing to report suspicious activities. A senior-level “hotline champion” who owns and oversees the program also reinforces its significance. The champion should be someone with authority to make decisions and act on tips; if the organization has an Ethics or Compliance Officer, that individual should be an ideal candidate.

SOLUTIONS AND RECOMMENDATIONS

From a managerial perspective, it must be recognized that the key aspects of any whistleblowing framework would be incomplete in the absence of supporting whistleblowing legislation and a supportive culture.

The Role of Whistleblowing Legislation

Within any management framework for whistleblowing, whistleblowing legislation is critically important for its effectiveness in identifying, reporting, managing, and rooting out corporate wrongdoing, while protecting the welfare and interests of the whistle-blower. Globally, across both the private and public sectors, whistleblowing policies to protect the organization, the whistle-blower, and to address organizational misconduct have undeniably been promoted as key aspects of the management of whistleblowing. Whistleblowing policies are relevant and can play a critical role in implementing management practices, which is a key ingredient of organizational growth. For example, in the United Kingdom, the Combined Code on Corporate Governance promotes the revision of arrangements by audit committees as it relates how employees can confidentially raise concerns about possible improprieties in matters of financial reporting or other matters, and to ensure that independent and proportionate investigative

arrangements are organized and the relevant follow up actions are undertaken. In the United States, the Sarbanes-Oxley Act, which provides guidelines for the operation and management of public companies, also highlights the enhanced responsibilities of external auditors, audit committees, board of directors and effective whistle-blowing mechanisms, for the protection of stakeholders and the public's interest.

Such whistleblowing policies have been shown to be much more effective however, in the presence of a specific and detailed whistleblowing legislative framework. To supplement the existing reporting mechanisms, there needs to be more protection for whistle-blowers in society and organizations, especially in an environment where there are high personal costs for reporting. This protection can come in the form of whistle-blower legislation which can incentivize whistleblowing and penalize wrongdoers and persons who obstruct whistle-blowers. The SEC's Whistle-blower Award is an example of the incentivizing of whistleblowing. In response, several countries globally have recognized the need to support and extend organizational whistleblowing policies through specific whistleblowing legislation. Most recently, on April 23, 2018, the European Union (EU) drafted a new law designed to strengthen the protections given to whistle-blowers across the bloc.

Other Examples of Whistleblowing Legislation

- United Kingdom Public Interest Disclosures Act, 1998
- Securities Exchange Commission (SEC) Whistleblowing Program, 2010
- Japan Whistle-blower Protection Act, 1994
- South Korea Anti-corruption and Protection Act, 2001
- New Zealand Public Service Whistle-blowing Act, 2000
- Whistle-blowers Protection Act in Australia (Victoria), 2001
- Protected Disclosures Act in Jamaica, 2011

Within such Acts, provisions are also made for a code of conduct, the protection of the whistle-blower, whistleblowing channels, procedures and support structures for, and programmes to promote whistleblowing. In the U.S and Australia, for instance, annual reports must be released specifying the current guidelines, the number of disclosures investigated and referred to other public agencies. In the U.S, as well, toll-free helplines have been opened for employees of private and public companies to report suspected misconduct or fraud. Notably, when whistleblowing policies are supported by whistleblowing legislation, not only a moral obligation, but a legal obligation is created to blow the whistle on corporate wrongdoing. Further, it promotes an environment of safety for whistleblowing within the ambits of the law.

Even in the face of such legislative frameworks, protection within the management of whistleblowing still needs work. For example, Hervé Falciani, a whistle-blower who leaked documents alleging widespread tax evasion at HSBC's private banking arm, has faced extradition requests from Swiss authorities. Howard Wilkinson, the former Danske Bank manager who alleged the bank was caught up in a €200bn money laundering scheme, called upon national governments to offer him greater protection after his identity was disclosed. Clearly, the safeguards in place to defend whistle-blowers against reprisals are insufficient. It is therefore, apparent that the majority of people around the world, speaking up about cases of wrongdoing in the workplace are perilous, and legal protection is insufficient even in the face of disclosure legislation. Many citizens still remain largely unprotected if they speak up, facing the risk of retaliation, judicial proceedings and dismissal. Such cases are further complicated where legal and ethical conflicts emerge in relation to whistleblowing.

The problem is that the protection afforded to whistle-blowers varies country by country and legal and ethical conflicts further complicate whistleblowing legislation. For example, in some nations such as the United Arab Emirates (UAE), whistleblowing legislation conflicts with defamation clauses in the country's penal code, and with the code of conduct and ethics of many organizations. Whistleblowing is not clearly defined by UAE law. In terms of the obligation to report wrongdoing, the UAE Penal Code contains a requirement that all individuals in the UAE report criminal activity. However, in practice, this requirement is not rigorously enforced and it also fails to address unethical practices or go on to provide protection from retaliation for those who report criminal activity. Accordingly, whistleblowing has traditionally been a less common practice in the UAE than in other developed jurisdictions, particularly in the U.S where whistle-blowers are not just protected but, in many cases, are incentivized to make disclosures.

It is therefore important that such legal and ethical conflicts are addressed within the management of whistleblowing. To do so, it is recommended that complementary codes of organizational ethics be established and aligned to universal legal frameworks to further minimize the need for external whistleblowing as well. There is the need for a unified global stance on the need for whistleblowing, the procedures to be followed for enforcement, and protection for all parties involved from an organizational and legal perspective. In Australia for example, whistleblowing protection laws in its final stages include fines for organizations that do not have whistleblowing policies and requires whistle-blowers to have objective grounds, not just "good faith" for so doing. Universal legislation alone therefore is insufficient and must function within organizational frameworks that promote organizational ethics.

The Role of Culture in Whistleblowing

In addition to a supportive legislative framework for whistleblowing and the promotion of organizational ethics, cultural factors can also play an important role in the acceptance and adoption of whistleblowing within particular organizations and societies. Organizational and national cultures determine how individuals perceive whistleblowing, but it also impacts how whistle-blowers are viewed and treated.

Organizational culture has been commonly defined as shared values, beliefs and assumptions among employees within an organization. Values and beliefs develop and evolve through the constant negotiation and practices among employees in an organization. These values and beliefs develop through time and provide a foundation for what is thought appropriate or inappropriate in a company with regards to right and wrong behaviour. Organizational culture therefore reflects the dominant ideology that exists within individuals' mind, conveys a sense of identity to workers and gives the unwritten and unspoken rules that instruct them on how to get along in their workplace. The organizational culture must be shaped to communicate to staff that whistle-blowing is accepted and unethical conduct will not be tolerated. Effective whistleblowing arrangements are an important part of a healthy corporate culture. But it is also crucial to have the right organizational culture which encourages people to speak out without fear. If the culture encourages principles of good corporate governance and shuns any form of organizational misconduct, an ethical climate can emerge. Further, if the organizational culture is open to, supports, and protects whistle-blowers, whistleblowing approaches and policies are likely to be much more effective in managing and rooting out corporate wrongdoing in such organizations. National culture frameworks such as Hofstede's Culture Consequences (1980) also acknowledge that across different societies and

countries, cultural norms and values can also impact upon the acceptance and success of whistleblowing. For instance, in collectivistic societies such as China, Hong Kong, Taiwan and various Caribbean countries, individuals are more inclined to act in accordance with the norms and interests of 'in-groups'. It is therefore expected that conflicts and face-to-face confrontations may be kept at a minimum. In this regard, it may be difficult for boards and shareholders to effectively function in their respective positions, given the conflict of interests that can arise as a result of close relationships formed in such societies. This suggests that employees in these particular societies may be reluctant to blow the whistle when the need arises. Scepticism may also exist about the reality of whistle-blowers' protection in these countries, even in the presence of a supportive legislative framework. It is imperative that organizations take into account such national culture differences across countries when developing and using whistleblowing mechanisms, such as whistleblowing processes, policies and legislative frameworks since such cultural differences can impact the relevance and usefulness of whistleblowing.

Other Recommendations to Manage Corporate Wrongdoing

Whistleblowing must also be managed within the context of other employee strategies aimed at enhancing employment relationships. Human resource management (HRM) practices such as recruitment and selection, as well as, training and rewards should be used as functions to support and complement whistleblowing mechanisms. Indeed, such HR practices should set the context for employment relationships in recognizing that corporate wrongdoing in the first instance should not be tolerated as a precursor to the management of whistleblowing.

Recruitment and Selection

Organizations, both private and public, should consider the ethical predisposition and ethical sensitivity of applicants in the hiring process so as to minimize tolerance of and actual corporate wrongdoing. More specifically, personality tests and integrity tests can be incorporated as part of the selection criterion for new employees. This initiative at the start of employment relationships can assist in creating an ethical environment, which can only lead to the enhancement of the organization's image and reputation in the long run.

Training and Rewards

Organizations can provide training and development opportunities focused on the resolution of moral issues, the implementation of company policies on ethics and the reporting of wrongdoing, and the institution of reward systems for ethical and reporting behaviours. Such training and reward opportunities can create an environment where organizational misconduct is minimized. It should be noted that the public interest is generally served when ethical behaviour is followed. Conversely, the failure to follow ethical behaviour can have negative implications for organizations and society. Organizations should therefore also develop and institute ethics committees responsible for ensuring that misconduct is reported and managed, while training employees on how to address ethical dilemmas within the committees and rewarding them accordingly.

FUTURE RESEARCH DIRECTIONS

The term whistleblowing is thought to have its roots in the act of police officers and referees blowing their whistle to halt suspected criminals and to stop an action respectively. In the corporate context today, whistleblowing has emerged as a powerful disclosure mechanism for identifying, exposing, managing and rooting out corporate misconduct.

Indeed, unethical and illegal corporate activities continue to plague societies. In future, it is expected that such activities will increase if left unchecked and unmanaged, with even more devastating effects than experienced in the last few decades. As such, there is an even more powerful role for whistleblowing in the future as white-collar crime continues to increase. There is a need however for all organizations to recognize that they must open up to scrutiny and disclosure. For too long, there has been limited recognition that managerial frameworks must be adopted to maximize the benefits of whistleblowing.

Future research, building from this work, should explore the symmetry between corporate wrongdoing or corporate misconduct and other criminal activities. Indeed, there may be spill-over effects from corporate wrongdoing into other areas of crime. This spill-over has the potential to exponentially increase crime and criminal activities beyond the boundaries of the organization. If so, such future research will reinforce the need for all organizations to embrace and maximize whistleblowing given its power to manage corporate wrongdoing.

CONCLUSION

Whistleblowing can provide the basis for managing, addressing, and preventing corporate wrongdoing and misconduct as a disclosure mechanism. Whistleblowing can not only help to reduce white-collar crime but can also prevent the collapse of organizations under the weight of fraud, corruption, and other forms of misconduct, which can lead to corporate bankruptcy as well. Even so, not many observers of corporate misconduct are willing to come forward and blow the whistle. This is partly due to the possibility of severe reprisal on the whistle-blowers by their peers and employers as a result of incriminating information on their employers. In spite of the high personal costs of whistleblowing on the whistle-blower, it is undeniable that a structured management approach must be taken to maximize the benefits of whistleblowing in addressing corporate wrongdoing, while also addressing the concerns of whistle-blowers.

A structured management framework must take into account procedures for identifying acts which constitute corporate wrongdoing or misconduct, reporting structures for the wrongdoing, the organizational response to managing, addressing and ending the wrongful acts revealed through reporting, and the organizational response to the whistle-blower. Such a framework must also take into account the relevance of whistleblowing legislation, the role of culture in enhancing the effectiveness of whistleblowing, and the impact of supportive HRM functions in establishing an ethical climate where organizational misconduct is discouraged.

Even so, no standard whistleblowing framework with supporting mechanisms may work for all organizations in the same way. However, it can provide the foundation for recognizing the power of whistleblowing in rooting out corporate wrongdoing.

KEY TERMS AND DEFINITIONS

Disclosure: The process of revealing something.

Enron: A company in the United States which went bankrupt in 2001 due to accounting fraud. It has been dubbed the worst accounting scandal in history, and it was exposed through whistleblowing.

HRM: Acronym for human resource management. A set of practices to attract, develop, and maintain an effective workforce.

Illegal: Actions or practices which are against the law.

Unethical: Actions or practices deemed immoral or wrong.

Whistleblower: An individual who reveals wrongdoing to some higher authority. Illegal and unethical activities are usually revealed by such a person.

Whistleblowing: The act of revealing wrongdoing to some higher authority. Illegal and unethical activities are using revealed.

Whistleblowing to Expose Criminal Activity in the Health Sector

Niyi Awofeso

School of Health and Environmental Studies, Hamdan Bin Mohammed Smart University, UAE

INTRODUCTION

Whistleblowing is the non-obligatory act of disclosing information about unethical or criminal activity in an organization. Although most instances of whistleblowing in the health sector relate to patient safety issues such as reporting on poor clinical outcomes involving a single individual over a period (Dyer, 2005; Bolsin et al, 2011), the health sector is not immune from criminal activity. Health care fraud – defined as an intentional deception or misrepresentation that the individual or entity makes knowing that the misrepresentation could result in some unauthorized benefit to the individual, or the entity or to some other party - is a major crime in most nations, accounting for 2% to 10% of total healthcare costs. In countries with universal health insurance such as UAE, health insurance fraud may account for up to 10% of total health insurance claims (Awofeso, 2017). The World Health Organization has cited fraud as one of 10 leading causes of inefficiency in health systems (WHO, 2010). The current global average loss rate of 6.19% attributable to health system fraud expressed as a proportion of 2013 global health budget of \$7.35 trillion equates to \$455 billion (Gee and Button, 2015).

In most other nations, (external) whistleblowing – leaking information to the press or independent healthcare complaints boards, for example, is discouraged due to reputational effects on the organization. Pertinent in this regard is the impact of vexatious whistleblowing, in which whistleblowers may accuse healthcare personnel of, for example, research fraud, without substantiating their claims – leading to incalculable damage to professional and organisational reputation (Wright, 2010). There is also a somewhat paternalistic reason why some organizations appear to discourage (external) whistleblowing – whistleblowers suffer substantial ostracization from colleagues and senior management, even if the whistleblower's accounts are true. (van de Verden et al, 2018). Whistleblowing situations are stressful and may cause physical and emotional health problems for both whistleblowers and non-whistleblowers (McDonald & Ahern, 2002).

Over the past three decades since the World Wide Web became established internationally, it has produced mixed results for both facilitating and preventing criminal activity in the health sector. With the expansion in online use of health care in payments, data storage and medical devices using online platforms, the risks to patient data confidentiality and cyberattacks on medical devices have increased exponentially. Since 2000, the American Medical Association has deemed internet healthcare ethics an important sector, and implemented principles governing websites that its members use for health related purposes, such as; “*Medical websites, more than any other type of site on the Internet, should ensure visitors' personal privacy and prevent personal medical information, including patterns of use and interests, from being sold, purchased, or inadvertently entering the hands of marketers, employers, and insurers.*” (Winker, Flanagi, Chi-lum et al, 2000). With internet technology being increasingly used in health care medical devices as well as in health care research, risks related to hacking of medical

DOI: 10.4018/978-1-5225-9715-5.ch021

devices and falsification of research data may increase. According to the 2018 Stericycle Recall Index report, there was a 126% increase in recalls of medical devices such as cardiac pacemakers between 2017 and 2018, mainly due to software hacking vulnerabilities (Stericycle Expert solutions, 2018). The use of internet-based media outlets enables whistleblower activities to reach every corner of the globe, with major adverse consequences for the organization and the whistleblower. These issues illustrate the nexus between healthcare, the internet and illegal or unethical activities.

Background

The role of the whistleblower in detecting healthcare fraud is perceived as important in some industrialized nations such as the United States, Australia and United Kingdom. For example, in the United States, Medicare processes over one billion fee-for-service claims per year through its contracts with regional insurance companies. Given the enormous volume of claims submitted under the Medicare program, the federal and state governments are not sufficiently staffed to effectively detect the fraud and abuse perpetrated by dishonest physicians, healthcare providers and suppliers. The Whistleblower Protection Act was made into federal law in the United States in 1989. The US Securities and Exchange Commission (SEC) has awarded more than \$262 million to 53 whistleblowers since issuing its first award in 2012. All payments are made out of an investor protection fund established by Congress that is financed entirely through monetary sanctions paid to the SEC by securities law violators.

Whistleblowers may be eligible for an award when they voluntarily provide the SEC with original, timely, and credible information that leads to a successful enforcement action. Whistleblower awards can range from 10 percent to 30 percent of the money collected when the monetary sanctions exceed \$1 million. In December 2017, Australia introduced The Treasury Laws Amendment (Whistleblowers) Bill 2017, which introduces a specific whistleblower protection and compensation regime for those who expose misconduct in public health and safety, tax and corporate fraud affairs. Public companies and large private companies that fail to set up internal whistleblower policies before 1 January 2019 risk facing penalties of up to 60 penalty units (currently A\$63,000 for a body corporate).

It is helpful to distinguish between internal whistleblowing, which entails employees reporting criminal or patient safety concerns to managers internal to their organization, from classic (external) whistleblowing, when an employee reveals information externally (or publicly) about wrongdoing within the organization, due to the ethical and consequential differences between both variants of whistleblowing. External Whistleblowers often end up choosing between failing in a duty to the public and failing in a duty to their employer, and they chose to fail in their duty to their employer, irrespective of whether the employer has a legitimate or moral standing in the issue concerned. Such violation of the *pro tanto* obligation to the employer impairs the moral standing of whistleblowers (MacDougall, 2016).

Ethical and Legal Aspects of Whistleblowing in Health Sector

Health care ethics is the field of applied ethics that is concerned with the vast array of moral decision-making situations that arise in the delivery of health services. Essential to the comprehension of moral issues that arise in the context of the provision of health care is an understanding of the most important ethical principles and methods of moral decision-making that are applicable to such moral issues. There are several core ethical approaches to understand whistleblowing in the health sector – utilitarian ethics, virtue ethics, organizational ethics, and deontological ethics. Utilitarianism is a variant of rule conse-

quentialist ethics, which posits that the morally right action is one with the best overall consequences. Whistle blowing may be supported by utilitarianism if it will benefit a significant number of people. A hedonic calculus may be applied to evaluate the harms and benefits of whistleblowing, but this approach is likely to underestimate the harms given that whistleblowing settings tend to affect an overwhelming majority of individuals in such settings. Internal whistleblowing reduces the harms caused by exposing misconduct (Wilmot, 2000).

Virtue ethics is one of three major approaches in normative ethics. It may be described as an approach that emphasizes techniques promoting an agent's character and instructing their conscience, may motivate whistleblowing particularly among individuals with a dominant (benevolent) superego (Nair, 2002). Integrity is a virtue that aligns with motivations to report wrongdoing. Most healthcare professionals code of ethics and conduct include the value of integrity. Thus, reluctance to engage in whistleblowing when there are compelling reasons to do so may violate the integrity virtue. Ironically, loyalty to organizations is one of the conditions of employment in many health organizations, and external whistleblowing may violate such employment condition, expressed as betrayal of trust (Pellegrino, 1995; CNA 1999).

Organization ethics includes various guidelines and principles which decide the way individuals should behave at the workplace. Fiduciary relationships (i.e. relational ethics) are integral to organizational ethics as they underscore loyalty, integrity and organizational structures. Fiduciary relationships exist between employer and employee, as well as between healthcare providers and patients. A conflict of loyalty usually implies a failure of organizational ethics and accountability since, under normal circumstances, both fiduciary relationships should be well aligned. Healthcare organizations that do not support whistleblowers reporting fraud or violations of professional standards suffer from a failure of organizational ethics. (Fletcher, Sorrell and Silvia, 1998; Ray, 2006).

Deontology is a variant of normative theories regarding which choices are morally required, forbidden, or permitted. It guides and assesses our choices of what we ought to do, and posits that the morality of an action should be based on whether that action itself is right or wrong under a series of rules, rather than based on the consequences of the action. Whistleblowers who align with a deontological approach view the act as a duty that needs to be undertaken as part of their moral and professional obligations, irrespective of its consequences. External whistleblowing in the health sector regarding criminal, fraudulent or patient safety grounds prioritizes loyalty duties to patients over and above loyalty to implicated colleagues or the organization as a whole. However, deontology is related to moral rules, not legal ones. In line with studies in other sectors (Keenan, 2000), deontological rules significantly motivate whistleblowing in healthcare settings.

The high profile media attention which whistleblowing has attracted across the world in recent years has underlined its relevance to all organizations. For instance, in 2013, an anonymous whistleblower sent an email to British pharmaceutical company GlaxoSmithKline (GSK) board members, external auditor, Chinese government and senior executives, describing fraudulent activities in China. The whistleblower stated that medical professionals were given all-expenses-paid trips under the pretense of attending professional conferences. Also, that the drug Lamictal was being heavily promoted as a treatment for bipolar disorder, despite being approved only for treatment of epilepsy by Chinese regulators. Bribes totaling \$9000 were allegedly paid to a patients who experienced adverse reactions to Lamictal in order to keep the patient's silence. In 2014, the company was fined \$489 million by Chinese courts for bribing doctors and hospitals to use its products and bribing government officials and regulators to ease monitoring of GSK. It is not clear what motivated the anonymous whistle blower, and whether he received any pecuniary benefit, or sanctions, for his actions.

In many nations in which whistleblowing is essentially a criminal activity, the internet has served as a vital vehicle for achieving the whistleblowers' aims. The legal system's general hesitancy to extend protection to media whistleblowers is reinforced by the perception that reporters and online internet sites are used by less "worthy" whistleblowers - those with groundless claims, those who are vengeful, and those with other ignoble motives (Callahan and Dworkin, 1994).

In the United States, The Securities and Exchange Commission won new powers in the 2010 Dodd-Frank Wall Street reform law to entice whistleblowers with monetary awards. A record \$30 million was paid to an anonymous whistleblower for helping to uncover large-scale fraud, essentially 10 – 30% of total amount recovered by the US government (Rickman, 2017). Among G20 nations, whistleblower protection laws are most explicit in USA, UK, Japan, and China but are less so in Germany and France. Australia's explicit whistleblowing protection law is currently undergoing deliberations in its parliament. Only USA, Japan and China explicitly provide protections for external whistleblowers. In the Middle East region, Bahrain has the most restrictive whistleblower laws. In the United Arab Emirates, whistleblowing is not currently protected at a federal level and in certain circumstances whistleblowing may potentially lead to both criminal and civil liability for breach of confidentiality and criminal liability for defamation. However, in Dubai, Dubai Law 4/2016 on Financial Crimes has some modest protections for whistleblowers in respect of certain financial crimes. The mapping of whistleblowing legislation for selected countries is shown below in Figure 1 (Piper, 2015).

Whistleblowing and Patient Safety Violations

Patient safety is essentially about policies, procedures and practices that guarantee the prevention of harm to patients - those that reduce the risk of adverse events related to exposure to medical care across a range of diagnoses or conditions (Clancy, Farquhar & Sharp, 2005). In the context of patient safety, whistleblowing commonly entails identifying incompetent, unethical or illegal situation in the workplace, and reporting it to someone who may have the authority to stop the misdeed. Often 'whistleblowing' is used as a term when a concern feels unwelcome or when it's external, and 'freedom to speak up' or 'raising concern' are seen as being at the softer end of the spectrum, when a staff member first identifies and reports incompetent practices which may or may not be illegal. In most countries, laws determine whether breaches in patient safety can have legal consequences for individuals and institutions. Major patient safety breaches fall under the category of tort, or personal injury. Negligence as a tort is the breach of the legal duty to take care which result in damage, undesired by the defendant, to the plaintiff. Tort law seeks to compensate victims of certain actions or inactions based on the breach of a legal duty that caused damages (Ramanathan, 2014).

Two interesting Australian cases of whistleblowing in relation to patient safety concerns occurred in the Macarthur Health Service in New South Wales and Bundaberg Base Hospital in Queensland. The nurse whistleblowing in both cases occurred consequent to dysfunctional clinical governance and incident reporting processes. The Macarthur health service is located in South-West Sydney, and incorporates Camden hospital, Campbelltown hospital and Queen Victoria memorial nursing home. On 5 November 2012, four employee nurses of the health service met with the state health minister, and reported cases of substandard clinical practices resulting in patient deaths and injuries. These nurses have previously utilized internal reporting systems such as incident reports, reports to line managers or referral of cases to relevant peer-review committees. However, they felt that their efforts were both unwelcome and ineffective in changing the health services' unsatisfactory patient safety trends. Even reports sent to the senior executive level of the health service as well as the New South Wales nurses association

were forwarded to the hospital middle management to investigate. The minister referred the case to the State's Health Care Complaints Commission (HCCC) to formally investigate. The investigation resulted in an analysis of 47 clinical incidents alleged to have occurred between June 1999 and February 2003. After 13 months of investigation, the HCCC report was delivered to the Director general of the health Department in December 2003. The published report strongly supported most of the allegations made by the nurses, e.g. "in some instances the care was so poor that patients suffered serious deterioration in health" (HCCC 2003, p4, part 1). In spite of these adverse findings, no prosecution or disciplinary action was recommended against those found to have breached their duties of care. The new health minister, Mr. Morris Iemma, decided to sack both the HCCC board and the then HCCC commissioner, Ms. Amanda Adrian. In all, there were five major inquiries costing many millions of dollars, and the devastation of scores of careers. At the end of it all, there have been big changes and more money for

the Macarthur Health Service. Yet only eight doctors faced disciplinary action. The outcome of the first case to go to the Medical Tribunal was announced this week. The doctor was reprimanded, but the judge said “his failure to act was in no way a gross dereliction of duty. In those circumstances it is somewhat surprising that a complaint was made to bring him before the Medical Tribunal.” In September 2015, the New South Wales Independent Commission Against Corruption produced the second of two reports into claims made by the four whistleblower nurses. It found that not one of the 39 serious allegations was substantiated. All four whistleblower nurses resigned from the Campbelltown hospital within two years. They reported adverse emotional consequences directly related to the case. According to one of them – Nola Fraser – “The personal effect was devastating: I couldn’t sleep for two years; I cried myself to sleep to think that those patients could have been saved if somebody just cared”. In late 2001 she went into intense therapy for 12 months. In March 2002, after yet another fight with her superiors, she walked out and went on extended sick leave due to depression and stress. As for Fraser’s former colleagues, most of whom won’t speak on the record, they are bitterly resentful. There are many stories of lives disrupted and long periods of depression. One said: “You’d think being investigated would be OK if you’re innocent. But it’s not. It’s traumatic.” By making many claims that were later proved to be wrong, the whistleblower nurses caused many people anguish. Nevertheless, they highlighted problems that deserve to be better known.

The Bundaberg Base hospital whistleblowing episode revolved around an Indian-born American surgeon, Jayant Patel, who was found guilty of gross negligence in 2005 whilst working at the 136-bed Bundaberg Base Hospital in a remote region of Queensland, Australia. Dr. previously worked with the renowned Kaiser Permanente hospital in Portland, USA. In his application to practice surgery at Bundaberg base Hospital, Dr. Patel fraudulently answered “No” to all application questions related to history of suspension or cancellation of his medical registration. Yet, the New York medical board for professional conduct suspended his license for 6 months and placed him on 3-year probation for entering patients’ histories and physical findings without actually examining patients, failing to maintain patients’ records, gross negligence, and harassing patients who were cooperating with the New York Board’s investigation (Bundaberg Hospital CoI Report, 2005). Patel was employed at the Bundaberg hospital between 2003 and 2005, during which he operated on about 1000 patients and performed about 400 endoscopic procedures. Nurses working with Dr. Patel repeatedly complained through internal channels such as occurrence variance reports about his sub-optimal level of surgical competence and associated high post-operative complications. Nurse Toni Hoffman formally complained about Dr. Patel to Bundaberg hospital directors of nursing and medical services in 2003 when he performed a complex operation – oesophagectomy – on two patients (P18 and P34) – although the ICU at the hospital was not equipped to provide artificial ventilation for more than 48 hours. Patient 34 died a few hours following surgery, while patient 18 suffered serious complications. After about a dozen other adverse clinical incidents involving Dr. Patel, an external clinical audit review was commenced at Bundaberg hospital in January 2005.

However, evidence for investigating the scope of practice and quality of Dr. Patel’s surgical outcomes were not initially collected. He even had his contract “temporarily” extended from 2005 to 2009. Following multiple ignored internal reports, Toni Hoffman decided to report Dr. Patel to Mr. Rob Messenger, local member of the Queensland Parliament, seat of Burnett. At the meeting with Mr. Messenger on 18 March 2005, Hoffman requested whistleblower status and expressed a desire to remain anonymous. On 22 March 2005, Mr. Messenger tabled Ms. Hoffman’s complaint at the Queensland parliament, leading to the implementation of two inquiries into Dr. Patel and Queensland hospital starting 26 April 2005. The health systems review highlighted a failure of organizational ethics in the Queensland health system, with strong themes highlighting bullying, intimidation, blaming and avoiding responsibility (Forster, 2005).

The Bundaberg hospital Commission of Inquiry (2005) was initially terminated on 2 September 2005 following a reasonable apprehension of bias against inquiry commissioner Morris. Following public pressure instigated by whistleblower Toni Hoffman, the inquiry was reinstated and a new commissioner, Geoff Davies was appointed. The inquiry castigated Bundaberg hospital management for failure to properly check Dr. Patel's background, and failure of credible incident reporting and complaints system. Commissioner Davies detailed nine specific charges against Dr. Patel, including performing surgical procedures restricted by previous medical boards and failure to report 13 deaths to the coroner. Davies recommended Dr. Patel to be investigated by Queensland police for "fraud", "negligent acts causing harm" and "manslaughter". Patel was extradited from the US to Australia and was convicted and jailed on all 3 counts. After two years of imprisonment, Patel was granted bail in 2012 after it was concluded that his trial was tainted by highly emotive and prejudicial evidence. In November 2013, Patel was given a two-year suspended sentence.

The head of a royal commission-style inquiry, former Supreme Court judge Geoff Davies, lauded Toni Hoffman as a hero in late 2005. He found her care, passion and courage were key in bringing to light a disaster, that led to at least 13 deaths and injuries to dozens of patients. At a personal level however, Toni Hoffman lamented that her career, health and psychiatric wellbeing were now severely affected because bureaucrats and successive ministers caused her to be increasingly shunned and ostracized. She claimed that she is being portrayed by Queensland Health and its corporate chiefs as "the untrustworthy nurse who embarrassed us all". Although she received the Order of Australia medal and Local Hero recognition in 2006, she claimed that she was threatened with "performance management" and left in no doubt that her career was at a standstill or worse. She eventually negotiated a payout compensation package with Queensland health service.

Whistleblowing and Health Research Ethics Violations

There is no generally agreed definition of research; however, it is widely understood to include at least investigation undertaken to gain knowledge and understanding or to train researchers. Human research is conducted with or about people, or their data or tissue. Human participation in research is therefore to be understood broadly, to include the involvement of human beings through taking part in surveys, interviews or focus groups, undergoing psychological, physiological or medical testing or treatment, being observed by researchers, and researchers having access to their personal documents or other materials. The relationship between researchers and research participants is the ground on which human research is conducted. Important ethical values in research include respect for human beings, research merit and integrity, justice, altruism, respect for cultural diversity and beneficence. These values help to shape that relationship as one of trust, mutual responsibility and ethical equality (NHMRC, 2018).

Research misconduct is defined as fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results. Research misconduct violates research ethics and integrity, and may mislead, harm and discredit the research community and the general public. Among ethics values, respect is central. It involves recognising that each human being has value in himself or herself, and that this value must inform all interaction between people. A classic example of violation of research ethics is the Tuskegee syphilis study among African American males - the longest nontherapeutic experiment on human beings in medical history. Begun in 1932 by the United States Public Health Service (USPHS), the study was purportedly designed to determine the natural course of untreated latent syphilis

in some 400 African American men in Tuskegee, Macon County, Alabama. The research subjects, all of whom had syphilis when they were enrolled in the study were matched against 200 uninfected subjects who served as a control group. The subjects were recruited with misleading promises of “special free treatment,” which were actually spinal taps done without anesthesia to study the neurological effects of syphilis, and they were enrolled without their informed consent. The subjects received heavy metals therapy, standard treatment in 1932, but were denied antibiotic therapy when it became clear in the 1940s that penicillin was a safe and effective treatment for the disease. When penicillin became widely available by the early 1950s as the preferred treatment for syphilis, this therapy was again withheld. On several occasions, the USPHS actually sought to prevent treatment (Heintzelman, 2003).

The project was reluctantly terminated after Peter Buxtun, a former PHS venereal disease investigator, shared the truth about the study’s unethical methods with Associated Press reporter Jean Heller. Congressional hearings into the conduct of the study led to legislation strengthening guidelines to protect human subjects in research (i.e. The Belmont Report). Fred Gray, a civil rights attorney, filed a \$1.8 billion class action lawsuit that resulted in a \$10 million out-of-court settlement for the victims, their families and their heirs. The research was generally adjudged to be so unethical that when in 1997 President Clinton was apologizing for it, he described it as “deeply, profoundly, and morally wrong” (Thomas 2000). Was the action by Buxtun of exposing the malpractices in the Tuskegee Study morally right or wrong? On what grounds do we judge this act of whistle blowing (and the press reporting by Jean Heller) as morally right or wrong? For a Kantian who believes that moral agents have a duty to be morally upright based on the notion of goodwill, such an action could be judged to be morally good (Ogungbure, 2011).

Peer review of research work submitted for publication in scientific journals is a longstanding approach for preventing publication of fraudulent data. However, peer reviewers cannot be expected to detect deliberate and blatant attempts to deceive them. Scientists generally trust that fabrication will be uncovered when other scientists cannot replicate (and therefore validate) finding. However, scientists struggle to replicate and reproduce findings from even highly cited journals. In a landmark article, Stroebe, Postmes, and Spears (2012) highlighted the importance of whistleblowers in uncovering criminal activity in research publications. For 21 of these forty cases they list a “whistle-blower” as the mode of discovery. A further two of the studied cases also entailed whistleblowers: William Summerlin was caught “painting his mice” but it needed the technician who caught him to report this misconduct to prompt Summerlin’s suspension and the formal misconduct inquiry. In the case of Ranjit Chandra, Stroebe and colleagues indicate that journal peer review was a contributor to his unmasking as a data fabricator in 2002. However, a whistle-blower (Marilyn Harvey) had reported him to the Memorial University authorities in 1994 and a subsequent confidential university committee report found him guilty of research fraud. However, no action was taken and he continued to publish fraudulent data for almost another decade.

Rather than being applauded, the experiences of the whistleblowers, as painstakingly documented by Dr. Geoffrey Webb (2018), paint a mixed picture. For example, in 2006, Eric Poehlman was became the first scientist in the USA to receive a prison sentence for activities relating to research fraud. He was convicted by a federal court in Vermont of making a false statement in a US federal grant application and was sentenced to a year and a day in prison. He had previously been fined \$180,000 and banned for life from receiving federal research funding. This case is highlighted because the whistle-blower received a \$22000 share of the \$180000 recovered from Poehlman by the federal authorities. Also Michael Briggs, a Professor at Deakin University, Australia, was unmasked a fraudulent researcher by Dr. James Rossiter, then chair of the ethics committee at Deakin University. Rossiter’s first action was in October 1983 when he reported his suspicions to the chancellor of the university along with a file of supporting

evidence. It was not until 1988 that a final report on the Briggs affair was eventually produced by the university – Briggs resigned from the university in 1985. Rossiter endured several years of intimidation and harassment for his whistleblower activity, but was eventually vindicated in the Deakin university's report (Rossiter, 1992). Also in Australia, the first case of criminal conviction for research fraud occurred in 2016 when Dr. Murdoch and Dr. Barwood of the University of Queensland were convicted on 5 and 17 charges of research fraud and attempted fraud respectively, following the actions of a whistleblower who demonstrated that the data were fabricated (QCCC, 2016)

Whistleblowing to Expose Health Care Fraud

Health care fraud is a type of white-collar crime that involves the filing of dishonest health care claims in order to turn a profit. Fraudulent health care schemes come in many forms. Practitioner schemes include: individuals obtaining subsidized or fully-covered prescription pills that are actually unneeded and then selling them on the black market for a profit; billing by practitioners for care that they never rendered; filing duplicate claims for the same service rendered; altering the dates, description of services, or identities of members or providers; billing for a non-covered service as a covered service; modifying medical records; intentional incorrect reporting of diagnoses or procedures to maximize payment; use of unlicensed staff; accepting or giving kickbacks for member referrals; waiving member co-pays; and prescribing additional or unnecessary treatment. Members can commit health care fraud by providing false information when applying for programs or services, forging or selling prescription drugs, using transportation benefits for non-medical related purposes, and loaning or using another's insurance card (Legal Information Institute, 2018).

When a health care fraud is perpetrated, the health care provider passes the costs along to its customers. Because of the pervasiveness of health care fraud, statistics now show that 10 cents of every dollar spent on health care goes toward paying for fraudulent health care claims. The World Health Report (2010_ estimated that about 20-40% of all health sector resources are wasted and highlighted health care leakages-waste, corruption and fraud-as the ninth leading source of inefficiency of health systems.

In the United States, according to the Federal Bureau of Investigation, healthcare fraud costs taxpayers over \$80 billion annually. From January 2009 through September 2013, the US federal government recovered \$17 billion in false claims alone. Federal and state laws that may involve whistleblowing include: False Claims Act (Qui Tam), 31 U.S.C. § 3730(h) – fraudulent billing by Medicare healthcare providers (hospitals, nursing homes, physician practices, etc.), drug and medical device manufacturers and suppliers; Georgia False Medicaid Claims Act, O.C.G.A. § 49-6-168 et seq. – fraudulent Medicaid claims submitted to the state Medicaid program; Fair Labor Standards Act, 29 U.S.C. § 218C (enacted Sec. 1558 of the ACA) – whistleblower protection for insurance company employees and others reporting violations of insurance reforms under Title I of ACA (e.g., prohibited coverage denials); False Claims Act (Qui Tam), 31 U.S.C. § 3729 – fraudulent bills or payments involving federal funds sent or made through a healthcare exchange established under the ACA; Stark Law/Anti-Kickback Statute, 42 U.S.C. § 1395nn (Stark), 42 U.S.C. § 1320a-7b(b) (AKS) – illegal referral fees or kickback arrangements between hospitals, surgery centers and healthcare facilities and physicians or other persons or entities for treating and referring patients for treatment; Sarbanes Oxley Act, 18 U.S.C. § 1514A – financial or other misrepresentations and fraud by public healthcare companies (for example, hospital operators); Occupational Safety and Health Act (OSHA), 29 U.S.C. § 660(c) – protection for employees and others reporting serious safety violations at healthcare facilities affecting patients or employees (violence against patients, inadequate care, unsafe conditions, etc.).

In an extreme case, a Detroit based oncology physician, Dr. Farid Fata, gave unnecessary treatments to 553 patients at a Detroit-area cancer center (Michigan, USA) in order to benefit from substantial health insurance claims totaling at least 17 million dollars. He was unmasked as a fraud by George Karadsheh, who took a job in 2011 as an office manager for Dr. Fata's rapidly expanding oncology practice in suburban Detroit. He was informed by another oncologist working in the practice and two nurse practitioners that patients were given chemotherapy and other treatments by Dr. Fata when they didn't have cancer. Karadsheh contacted an attorney – David Haron - he knew who handled whistleblower cases. Haron wasted no time and called the Department of Justice. George Karadsheh was willing to put everything on the line. "My job was at stake. My livelihood," he explained. "Even my own personal safety. "I wasn't looking at the patients anymore as being treated," Karadsheh said. "I looked at it as a burning building with people inside. ...I had to make it stop and I had to make it stop quickly. When he filed a lawsuit under the False Claims Act on Aug. 5, 2013, the so-called qui tam civil lawsuit joining Karadsheh and the government as co-plaintiffs — he triggered a legal process. Dr. Fata was convicted and sentenced to 45 years in prison for health care fraud. Dr. Fata pleaded guilty to sixteen counts—thirteen counts of health-care fraud, one count of conspiracy to pay and receive kickbacks, and two counts of promotional money laundering. He is currently appealing his sentence (US Sixth Circuit, 2016). George Karadsheh had been a federal whistle-blower before, and was very familiar with the legal processes involved. Government whistle-blower laws, including the False Claims Act used in this case, create a path for private citizens to help the government. The law requires secrecy for two reasons: to protect the government's investigation, and to protect the whistle-blower from retaliation and from contest to a financial stake in the outcome. In the Fata case, where the convicted doctor has surrendered more than \$10 million to the government, Karadsheh's share of 15-30 percent is at least \$1.5 million. The financial reward is rarely the sole motivation. The reward is taxable; lawyers typically get 20 to 30 percent; and whistle-blowers typically lose their jobs.

FUTURE RESEARCH DIRECTIONS

The internet, and associated utilization of health information systems management has been a major asset in improving medical documentation, simplifying payments and financial management, enhancing the scope of medical research using data linkage techniques, developing digital health technologies as well as internet monitored medical devices – Internet of Things. Largely unanticipated risks related to these benefits include: cybersecurity threats which may lead to theft of sensitive patient data and their sale on the dark web; financial internet fraud which may lead to diversion of large amounts of health care organizations' money into private accounts by criminally minded staff and external associates; medical research fraud, which is somewhat made easier by the use of internet resources to falsify data; and cyberattacks on internet controlled medical devices (Trend Micro, 2017). Contemporary health sector whistleblower activities are also strongly related to the use of the Internet, especially social media and online media outlets. Understanding factors that motivate whistleblowers in the health sector to utilize social or online media channels to publicize their concerns globally is an area worthy of research.

Future research directions should aim to adequately understand the scope and depth of vulnerabilities faced by health care sector in relation to whistleblowing and the use of internet or dark web, and to introduce appropriate ethics training, internal policies, cybersecurity upgrades, and appropriate comprehensive

and adaptive legislation which address the nexus between whistleblowing and the internet, in order to reduce its risks and maximize its benefits. For example, laws on external whistleblowing may require reporting first to institutional anti-corruption, regulatory boards and not to internet-based media, given the irreparable damage that such reports may cause to organizations if the whistleblower's claims turn out to be inaccurate, or if the reporting is motivated by vengeance or other ignoble aims.

In the area of financial fraud, web-based approaches for preventing financial fraud in healthcare settings, such as data mining based on Knowledge Discovery from Databases (Joudaki, Rashidian, Minaei-Bidgoli et al, 2015) should be explored for adaptation and general application. Internal controls in the form of policies and procedures are also important for controlling financial fraud in the health sector, most of which are currently carried out through illegal online funds transfers. For example, Hohepa Morehu-Barlow, a finance officer with Queensland Health, Australia, defrauded his employee to the tune of \$16.69 million in 65 fraudulent transactions between October 2007 and December 2011. A single fraudulent online transaction of \$11 million of public funds paid to Healthy Initiatives and Choices (HIC), a trading name registered to Hohepa in November 2011 raised audit queries which eventually led to his conviction (Crime and Misconduct Commission Queensland, 2013). Research geared towards the development of best practice standards internal audit controls is essential to prevent health care financial fraud.

Fraud related to research misconduct in healthcare requires renewed and expanded oversight powers devolved to Institutional Health Ethics Boards. An example of such expanded oversight powers relates to the ability to monitor research that is already approved in order to deter, detect and reduce health research fraud (Pickworth, 2000). Online tools such as protocols to detect fraud in web-based online research are particularly pertinent (Ballard, Cardwell and Young, 2019).

CONCLUSION

Whistleblowing may count as a crime or a virtue depending on the setting. Paramount in whistleblowing activities is the need to ensure that a violation has indeed been committed before reporting internally or externally. Healthcare workers have a responsibility to raise concerns about patient safety and unethical or illegal conduct. Yet, as shown by several of the case studies discussed in this chapter, those who raise serious concerns are often treated badly by senior colleagues, their employing organisations and the bodies that should protect whistleblowers. This paradox is because whistleblowers raise concerns that, if made public, would embarrass the organisation or senior and powerful individuals, who are considered less dispensable than the whistleblower. This chapter shows that whistleblowing is a vital instrument in uncovering criminal activity in the health sector, and may be superior to traditional approaches such as the longstanding use of peer review in excluding fraud in research work.

In nations where expressly stated legal whistleblower protections exist, and where external whistleblowers who correctly report criminal conduct are duly compensated financially, external whistleblowing may be worth the risks. Generally, internal whistleblowing represents the ideal approach to raising concerns about criminal activity. For internal mechanisms to be credible, high standards of organizational ethics and governance are indispensable. Criminal activity in the health sector is rare but carries significant risks for patient safety and financial sustainability of healthcare organizations. Internal and, rarely, external whistleblowing may facilitate risk management efforts for this significant leakage of health care resources.

KEY TERMS AND DEFINITIONS

Criminal Negligence: Reckless disregard for the lives or safety of other persons. In health care contexts, healthcare providers have a fiduciary responsibility for providing appropriate treatment to patients under their care. Many nations have laws that make overt negligence in the provision of healthcare a criminal offence.

Health Research Fraud: Intentional misrepresentation of the methods, procedures, or results of healthcare research. Behavior characterized as scientific fraud includes fabrication, falsification, or plagiarism in proposing, performing, or reviewing scientific research, or in reporting research results. Health research fraud is unethical and often illegal. A good example of such fraud with major ramifications is the measles-autism link published in the lancet but retracted in 2010 when it was confirmed that the study was conducted dishonestly and irresponsibly, using bogus data. Nevertheless, this erroneous link is partly responsible for increasing refusals of Measles containing vaccines by parents.

Healthcare Fraud: An intentional deception or misrepresentation that the individual or entity makes knowing that the misrepresentation could result in some unauthorized benefit to the individual, or the entity or to some other party Healthcare fraud refers to illegal acts of misrepresentation and false claims in order to receive undue financial or healthcare advantages. Health care fraud accounts for between 2 and 10% of wasted health resources globally. The World Health Organization cites healthcare-related fraud as one of 10 leading causes of inefficiency in health systems. Web-based healthcare fraud is a major challenge, especially when signatories to health organizations' accounts siphon money into private bank accounts. Regular audits and electronic monitoring systems such as e-claims management services help to monitor and prevent healthcare fraud.

Patient Safety: Initiatives to assure freedom from accidental or preventable injuries produced by medical care. Emphasis is placed on the system of care delivery that prevents errors, learns from the errors that do occur, and is built on a culture of safety that involves health care professionals, organizations, and patients. With the expansion of internet technology in the use of medical devices such as cardiac pacemakers, patient safety is increasingly vulnerable to web-based attacks, which have serious repercussions.

Raising Concerns Policy: Otherwise labelled “freedom to speak up” and “internal whistleblowing” such policies provide standardization of internal channels for speaking up about illegal or unethical practices and provide support and required anonymity for the employee who raises a concern.

Relational Ethics: A contemporary approach to ethics that situates ethical action explicitly in relationship. An important context of such relationships is within organizations, in which employees and employers have roles and responsibilities. Organizational policies and codes of conduct (and in some nations, anti-defamation laws) usually explicitly prohibit employees from discussing or exposing company secrets to the media or third parties without management approval. Thus, external whistleblowers are implicitly violating the relational ethics of such organizations.

Veracity: Conformity to facts; accuracy. Veracity is often difficult to establish in whistleblowing contexts since most whistleblowers have only limited information on a specified issue. Consequently, a significant proportion of external whistleblowing incidents have been found to be false. Contemporary whistleblowing laws such as the 2019 law in Australia require whistleblowers to provide objective evidence as condition to raising concerns internally or externally.

Virtue Ethics: Person rather than action based ethical conduct. It analysis at the virtue or moral character of the person carrying out an action, rather than at ethical duties and rules, or the consequences of particular actions. When morally orthodox and benevolent, virtue ethics is closely aligned to the ethical principle of deontology – fulfilling a virtuous moral duty. Many whistleblowers claim that their decision to expose alleged wrongdoing in their organizations were motivated by the desire to act according to their moral character to prevent harm to innocent others.

Whistleblowing: Non-obligatory act of disclosing information about unethical or criminal activity in an organization. Internal (intra-organizational) whistleblowing is less damaging to organizational credibility and the careers of whistleblower than external whistleblowing – reporting to the media or anti-corruption or institutional ethics boards. The term whistleblower comes from the whistle a referee uses to indicate an illegal or foul play. Ralph Nader coined the phrase in the early 1970s to reduce stigmatization of individuals who report illegal activity, any of whom were at the time referred to as “rats” and “snitches”. There are no public cases of cybersecurity whistleblowers on record to date, but in countries like the United States where large organizations have minimum mandatory cybersecurity requirements and payments of up to 30% may be received for whistleblowing acts which lead to recovery of assets from the Securities and Exchange Commission, a strong potential exists for such cases to emerge.

Online Activism to Cybercrime

Anita W. McMurtry

Curtis L. Todd

Atlanta Metropolitan State College, USA

INTRODUCTION

Hactivism is a socially or politically motivated act of misuse of computer systems, the internet, or a technology hack; which can be traced three decades back to 1989, when DOE, HEPNET and SPAN (NASA) connected VMS machines worldwide and were penetrated by the anti-nuclear WANK worm (Moore, Shannon, & Brown, 2002). Subsequently, it appeared on criminal justice systems' radar from law enforcement, to the courts, and then to corrections. There is a new imperative to not only gain a better understanding of the intricacies of this problematic behavior when it rises to criminal activity, but also how best to safeguard society in general, as well as national and international public and private businesses, organizations and governmental agencies. This entry moves beyond mere definitions of how what was once considered another form of legitimate protest and activism by delving deeply into the psychology and practical ramifications of its emergence, which has quickly morphed into problematic cyber behavior and criminal activity perpetrated through the improper use of technological tools and digital platforms.

To construct a solid operational understanding of Hactivism, this entry first extends its context as a cybercrime to include a global perspective, as well as hacker cultural and ethical mindsets. Second, inherent dangers, as it relates to critical areas such as political elections, industry and corporations, international affairs, personal data, and national security, are explored to further contextualize Hactivism's evolution and real-world challenges in identifying, investigating and prosecuting criminals. Also, legal issues and implications for criminal justice systems are explored to firmly anchor the urgency in moving this virtual issue to the center of priorities. Finally, informed suggestions, recommendations and future research directions are provided.

HACKTIVISM: A CONTEXTUAL DEFINITION

Derived from combining the words "hack" and "activism", the term "Hactivism" was first coined in 1996 by Omega, a member of the hacker collective Cult of the Dead Cow (Dyer, 2018). The group created an organization espousing that freedom of information was a basic human right. The group designed software to circumvent censorship controls on the Internet that some governments used to prevent citizens from seeing certain content. Hactivism is mainly portrayed in society as the transposition of demonstrations, civil disobedience, and low-level information warfare into cyberspace (Dyer, 2018). Hactivists

DOI: 10.4018/978-1-5225-9715-5.ch022

are the modern equivalent of political protesters, and the rise in hacktivist activity may be due in part to the growing importance of the Internet as a means of communication. Besides hackers who are in it for profit, there are hackers who break into systems to point out security flaws, and there are those who want to bring attention to a cause. The latter however, typically come in the form of virtual political activists who have adapted their methods of dissent into digital platforms, an act known as Hacktivism. Individuals proclaiming themselves as “hacktivists” often work secretly, sometimes operating in discreet groups while other times operating as individuals with cyber-world identities all consistent with the stated purpose of gaining public access and power in today’s society (Sengupta, 2012).

BACKGROUND

Hacking originated in the 1960s via the Tech Model Railroad Club at Massachusetts Institute of Technology (Leeson & Coyne, 2005). These computer scientists were charged with “hacking” switch control systems of model trains, increasing their speed, making them more efficient. At this time, Artificial Intelligence was also introduced and brought about the first large mainframe computer system. Hacking became the solution in solving issues of the mainframe computer providing shortcuts and allowing the system to run quicker and simpler. Hacking in its infancy had little to do with malicious intent. The original goal was to advance computer usage and not impair it. Hacking then became a means of personal gain in the 1970s using phone systems. This activity was known as Phreaking, which is the act of carrying out illegal activity via the telephone system (Pavlik, 2017). Hacker gangs developed in the 1980s with the Milwaukee area’s 414 gang. These noted individuals were able to access unauthorized outside computer systems and cause serious damage and disorder. The 414 gang is one of the first to be detained legally for their cyber-crimes (Leeson & Coyne, 2005). Consequently, in 1984, the government made it illegal to gain unofficial entry into a computer system.

Hacking is prevalent not only on computer systems, but the Internet as well. Cornell University was impacted by an Internet worm named Morris in 1988. The offender was sentenced to three years of probation (Leeson & Coyne, 2005). In the 1990s the pressing need to control the massive growth of the hacker occupation birthed the Federal Government to plan a series of raids in 14 cities known as “Operation Sundevil.” The notion that the majority of hacking involves pranks by pubescent boys or inconsequential crime is outdated. Organized crime hackers seek more lucrative initiatives. Russian hackers also stole \$10 million from Citibank, and the Federal Government responded in 1998 through the creation of the National Information Infrastructure Protection Center. Hacking overall is a worldwide phenomenon and is projected to become worse overtime. Denial-of-Service (DDoS) attacks that shutdown systems of enterprises such as Yahoo!, eBay, and Amazon, cost the global economy billions in lost revenue. Hacking comprises of breaching passwords, generating e-mail bombs, DDoS intrusions, scripting and circulating viruses, worms, and Trojans, screening prohibited intellectually property, URL redirection, and web defacement (Leeson & Coyne, 2005).

Cyberattacks have gained national and international attention. In 2008, a group named Anonymous opened a number of cyberattacks to assist a range of political and social issues. The focus and purpose of the group spans from commercial to government to religious organizations. On January 7th, 2013, Anonymous issued a “We the People” request asking the White House (United States of America) to acknowledge dispersed denial-of-service (DDoS) incidents as an endorsed form of demonstration safeguarded by the First Amendment of the United States Constitution (Li, 2013). Alongside Anonymous’ position, commentators posit that Hacktivism expands to digital civil disobedience, even if success is

gained by means of disturbance of circulation of data. Current trends in cyberattacks are questionable to warrant First Amendment consideration. Research also implies that Hacktivism may develop over time to fall within the scope of First Amendment defense. An absolute ban on all methods of Hacktivism may take up socially prolific practices of cyberattacks as a manner of protest (Li, 2013).

In the age of global capital, a concise focus from the criminal justice system is paramount. A complete global interest on the issue of cybersecurity has yet to be developed to effectively protect the cyber realm. Trans-national law enforcement practices in 'cyberspace' are necessary in maintaining cybersecurity. New networks are needed and the relationship between the government and other agencies will need to span across our national borders. Improvements are underway amongst nations to cultivate the strength of the international police in order to respond to cybercrime and education regarding the ground level security measures (Broadhurst, 2006). As a result, scholars and practitioners with a vested interest in alleviating the issue of malicious attacks are encouraged to 'think globally - act locally.' The Council of Europe's Cybercrime and the United Nations against Transnational Organized Crime are consistently vying for a worldwide standard of civil protections. Critical infrastructure and critical information infrastructures must be protected globally to protect the government and other systems from various security breaches. Thus, hacktivist may view the lack of attention and care as fertile ground for planting and cultivating a message or ideology (Broadhurst, 2006).

HACKING IN THE 21ST CENTURY

Hacking practices in the 21st century consists of modifying computer hardware and digital devices. Hacking in today's culture also requires new and more powerful resources as well as education via forums as Web 2.0 services. The I-phone and I-pad are significant suppliers in the spread of hacking culture amongst consumers. In answering the newly set boundaries, the I-phone operative scheme was "hacked" with the intention of permitting consumers to connect functions not authorized by the original owner. The message of this I-phone adjustment can also be coined as "jailbreaking," emphasizing the restriction of Apple's software and the permissive tone of alteration (Magaudha, 2010). Kirsch (2014) also notes the 2013 Target breach immensely disturbing one third of the United States. According to the FBI, similar attacks will increase even in the midst of efforts, fueling the platform of using cyberspace for nation state and non-nation state purposes.

POTENTIAL DANGERS TO DEMOCRACY

Hacktivism generally operate under a non-political umbrella and express self or group defined ideas without them being analyzed by the society at large. Their anonymous identities give them a sense of declared power to represent or defend matters of concern that they feel are important to them and their communities. Lately, however, the Hacktivism term has been applied to protests against multinational organizations, governments, and even rural law enforcement agencies, and the tactics now include denial-of-service attacks on sites, as well as leaks of confidential documents to the public. Although hacktivists typically go after non-retail organizations, the fallout from these attacks can still affect millions of people. In order to carry out their operations, they have the capacity to create new technology or integrate or use a variety of software tools that are readily available on the Internet. Hacktivism may be used as a substitute for or complement to traditional forms of activism such as sit-ins and protest marches. This

has happened with the Occupy Wall Street and Church of Scientology protests, which involved both the physical presence of supporters in the streets and online attacks (Aviles, 2015). Hactivist attacks, in and of themselves, are not violent and do not put protestors at risk of physical harm – unlike participating in a street protest – but in some cases, Hactivism might incite violence. It also makes it possible to support geographically distant causes without having to travel there and makes it possible for geographically dispersed people with common goals to unite and act in support of a shared goal. Hactivists represent many categories and classes of hacking for the sake of activism. It disturbs certain segments of society when it becomes a source involved in illegally accessing someone’s digital information for a political or social cause (Lindgren, 2011).

POLITICAL ELECTIONS

Hactivists have gone after everyone from foreign governments and corporations to drug dealers and pedophiles. Police departments, hospitals, small towns, big cities and states also have come under attack. Online activists have successfully frozen government servers, defaced websites, and hacked into data or email and released it online. The general category for this type of hacker would be a “Grey Hat” Hacker. One class of hactivist activities includes increasing the availability of others to take politically motivated action online to influence desired outcomes involving actors of broad nation states, oligarchs, or private organizations. Political activism is nothing new, but taking it online through covert tactics is a major change. It does not matter whether one views hactivists as dangerous enemies of the state or as digital ‘Robin Hoods,’ stealing information from the powerful and distributing it to the masses, the truth is that Hactivism can sway public opinion (Lindgren, 2011). However, a hactivist must find vulnerabilities within a system before covert political actions can take place.

American political elections are often the targets of threats by Russian, Chinese, and Iranian hactivists. Political elections are public and overseen by individual states and administered by local municipalities. Many of the voter systems are out of date and plagued with a variety of weaknesses. Efforts on behalf of the federal government to harden these voting systems have, in some cases, been met with suspicion by local and state officials wary of losing their autonomy. The U. S. Department of Homeland Security (DHS), the federal agency in charge of election security, indicates that they can help states or municipalities only if they request assistance; however, its recommendations, like those of other federal agencies, are not mandatory. But local election officials often lack the expertise needed to evaluate their systems’ liabilities and in addition, they have been known to be careless about securing those systems: software updates go uninstalled; machines are left unguarded and unlocked; and election programming and vote tabulation are often outsourced to third-party vendors that may have their own exposures (Leithauser, 2012). Americans, feeling victimized by election hacking, are more aggressive than ever in voicing concern and questioning over what is being done beyond government actions to prevent elections hacking. While the response describing the implementation of the DHS Cybersecurity agency was cited the most, other actions are receiving notoriety: social media firms are aggressively tampering down the use of their entities in campaigns; states with extremely large populations are attempting to pass election security policies; and both public and private firms are committing themselves to using smart technology to monitor foreign actors. An increase in new Hactivism is now the top anti-establishment online tool for achieving a diverse set of causes around the globe. Hactivists are deploying a range of tactics from temporarily shutting down servers to disclosing personal records and corporate information (Klein, 2015).

PERSONAL RECORDS

A group of nearly 3000 hacktivists under the name “Operation Payback” are on record as launching online attacks against PayPal, MasterCard, and Visa, briefly knocking the three financial services’ sites offline and attempting to prevent consumers from accessing their online banking and financial services. The hacktivists retaliated against the three companies for severing ties with WikiLeaks, an online repository for whistleblower data that had recently included thousands of secret communications from the U.S. State Department and other world governmental agencies (Anonymous, 2016). The key components of this operations involved records consisting of financial statements, income statement, balance sheet, and statement of cash flows. As a whole, these financial statements are designed to present a complete picture of the financial condition and results of a person or a business. A case can be made for each of the financial statements being the most important, though the ultimate answer depends on the needs of the user or their value to another interested party. The key points favoring each of these financial statements as being the most important to a hacktivist are income statements, balance sheets, and statement of cash flow.

The most important financial statement for the hacktivist is likely to be the income statement, since it reveals the ability of a business to generate a profit. Also, the information listed on the income statement is mostly in relatively current dollars, and so represents a reasonable degree of accuracy. The balance sheet is likely to be ranked lower by hacktivist, since it does not reveal the results of operations and some of the numbers listed in it may be based on historical costs, which renders the report less informative. The balance sheet is of considerable importance when paired with the income statement, since it reveals the amount of investment needed to support the sales and profits shown on the income statement. The best candidate for most important financial statement to the hacktivist is the statement of cash flows, because it focuses solely on changes in cash inflows and outflows (Schwartz, 2012). This report presents a more clear view of an individual or company’s cash flows than the income statement, which can sometimes present skewed results, especially when accruals are mandated under the accrual basis of accounting. The two statements that provide the most information to the hacktivist are the income statement and balance sheet, since the statement of cash flows can be constructed from these two documents. There are various ways hacktivists could exploit this type of information. The most common and easiest way is to simply print and write fraudulent checks in the name of the target, but unlike hackers for illegal gain, hacktivist usually operates on a higher level of morality that is aimed at highlighting injustices or frauds that are being perpetrated on the masses or those perceived as innocent victims (Schwartz, 2012).

TRADE SECRETS

Trade secrets theft or related exposures are often thought to be a ripe area for hacktivists activities. A trade secret is a formula, practice, process, design, instrument, pattern, commercial method, or compilation of information not generally known or reasonably ascertainable by others to the degree that a business can obtain an economic advantage over competitors or customers. Trade secrets can include advertising strategies, sales methods, and manufacturing processes. They also can be industry-specific, such as a company’s food or drink recipe. For example, the recipe for Coca-Cola is probably one of the most famous and well-kept trade secrets in the world today. The trade secrets theft industry – with consumers, suppliers, and information systems – is thriving on the data collected and stolen from electronic archives. There is a major market for stolen trade secrets and data relating to business advancements;

the technicians who do the hacking are not the ones who collect the data and do the collating and automating the fraud and subsequently collecting the profit. Threat actors come in many forms: malicious insiders, competitors, nation states, transnational organized figures and hacktivists (Dissecting a hacktivist attack, 2012). Hacktivists seek to expose sensitive corporate information, potentially including trade secrets, to advance political or social ends. These groups have used cyber intrusion skills and data gleaned from disgruntled insiders to obtain and publish Personally Identifiable Information (PII) and sensitive business information of key executives, employees, and business partners. Hacktivists have the technical knowledge and capabilities to steal trade secrets, and they could partner with other threat actors for ideological or financial reasons. Intentional theft of trade secrets can constitute a crime under both federal and state laws (Bradshaw, 2011).

The most significant law dealing with trade secret theft is the Economic Espionage Act of 1996, which made the theft, transmission, or receipt of trade secrets a federal crime. Many states have also enacted laws making trade secret infringement a crime. Corporate executives around the world regularly make decisions based on expectations about the future. Choices related to new product launches, expanding strategic business relationships, investment in capital projects, and research and development expenditures are each grounded, in part, on companies' expectations about the future. The challenge of trade secret theft is too large for any one government, company or organization to deal with alone. Only a collective focus on this issue will help improve innovators' ability to secure their most critical information and intellectual property (Bradshaw, 2011). Hacktivist might be involved in stealing or sharing trade secrets in an attempt to expose a company's unfair treatment of a class of individuals or some specific wrong doings.

ECONOMIC PROSPERITY

The economy is the process or system by which goods and services are produced, sold, and bought in a country or region. The U.S. economic environment is characterized by specializing in producing public goods and finances these goods with different revenue streams. Public goods benefit a large group of people and are collectively used by anyone. Goods can be owned exclusively and enjoyed individually, and can be bought and sold in market transactions; the ability to pay determines their allocation. The U.S. economic crisis resulted in social activism and provides ripeness for Hacktivism. The Occupy Wall Street Movement reflected social trends against economic inequality, which was intensified by the economic crisis. The main purpose of this social manifestation was to demand more political and socio-economic equality. They believed that larger corporations and global financial banks were misrepresenting the lower and middle class during the economic crisis. Further, it asserted that telecommunications and its associated technology not only contributes to economic weaknesses, but also affects intelligence operations (collection, analysis and dissemination) and promotes the complexity of war ramifications. Correspondingly, this lays a formidable foundation for hacktivist intervention (Aviles, 2015).

EFFORTS TO COMBAT HACKING

Law enforcement have made remarkable strides in contesting hacking throughout the country and globally. New systems connecting patrol and other organizations within government, systems connecting police and private organizations, and systems of patrol throughout the country's boundaries. Globally, two innovative treaty resources supply a complete foundation for the necessary cross-border patrol and

agent collaboration necessary in fighting cybercrime. The first resources, the Council of Europe's Cyber-Crime Convention, developed through resolution and aimed as an area contrivance with international credibility. The latter is the United Nations Convention against Transnational Organize Crime, which is universal in reach but circuitously manages Cybercrime when implemented by criminal associations in connection to serious crimes (Sangkyo & Kyungho, 2014).

In 2002 the Cybersecurity Enhancement Act provided a provision for privacy protection and a computer crime sentencing detail guide for enhanced penalties. In 2009 China brought forth an Amendment to the Criminal law of China (VII), which added "Hacker" to the Criminal code in order to be able to legally punish hacking. Shortly after in 2011, the Supreme People's Court held a trial to increase penalties for buying and selling materials for hacking purposes. After the trial, acts such as providing software would be punishable for up to ten years. Table 1 provides a comparison of each country's criminal law.

THE COMPUTER FRAUD AND ABUSE ACT

Computer crimes are primarily addressed by the Computer Fraud and Abuse Act of 1986 (CFAA). The CFAA makes it unlawful for any person to access a protected computer without authorization. It also forbids a person who has a legitimate and authorized right of access from exceeding the authorized access. If either type of access results in the person's obtaining information from the protected computer and the conduct involves interstate or foreign communication, then a violation of the Act is established. The CFAA also prohibits activities such as the dissemination of malicious software and trafficking in stolen passwords. The CFAA allows any person who suffers damage or loss by reason of a violation of the statute to maintain a civil action to obtain compensatory damages and injunctive relief or other equitable relief (Milone, 2013).

USA PATRIOT ACT

United States' President George W. Bush signed the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 (USA PATRIOT Act) into law on October 26, 2001. This Act of Congress provides law enforcement with sweeping powers and raised concern among privacy advocates. In essence, the Act seeks to protect the national infrastructure

Table 1. Comparing each country's criminal law

	Korea	Germany	USA	China
Legislation	Network Act, 48	Criminal Law, 202(a)	CFAA (18 U.S.C 1030)	Criminal Law, 285
Criterion for punishment	Access abusing their authority	Access without authorization	Exceeds authorized access	Intrusion actions
Penalty (imprisonment)	3 years	3 years	Over 10 years	3-7 years
Feature	In distributed laws	In Criminal Law	Severe punishment	Punish acts of indirect

Sangkyo, O. Kyungho, L. (2014). The Need for Specific Penalties for Hacking in Criminal Law. Retrieved from <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4083268/>

by easing the restrictions placed on electronic surveillance and facilitating the prosecution of cybercrime by amending many provisions in the CFAA. These amendments lower jurisdictional hurdles relating to protected computers and damages, and increase penalties for violations. Expanding the scope of “protected computers.” Before the amendments in section 814 of the Act, the CFAA defined “protected computer” as a computer used by the federal government or a financial institution, or one used in interstate or foreign commerce or communication. This definition did not explicitly include computers outside the United States. Because of the interdependency of global computer networks, system crackers from within the United States increasingly targeted systems located entirely outside of this country. In addition, computer criminals in foreign countries frequently routed communications through the United States as they gained access from systems located in one foreign country to another. In such cases, the lack of any U.S. victim discouraged U.S. law enforcement agencies from assisting in any foreign investigation or prosecution. Section 814 of the Act amends the definition of “protected computer” to clarify that this term includes computers outside of the United States, so long as they affect interstate or foreign commerce or communication of the United States. This allows the United States to use speedier domestic procedures to join in international computer crime investigations. In addition, the amendment creates the option, where appropriate, of prosecuting such criminals in the United States.

The CFAA previously had no special provision that would augment punishment for criminals who damage computers used in connection with the judicial system, national defense, or national security. Thus, federal investigators and prosecutors did not have jurisdiction over efforts to damage criminal justice and military computers where the attack did not cause over \$5,000 loss or meet one of the CFAA’s other special requirements. These systems, however, serve critical functions and arguably justify felony prosecutions even where the damage is relatively slight. Amendments in section 814 of the USA PATRIOT Act also created a section to address this issue. Under this provision, a criminal violates federal law by damaging a computer “used by or for a government entity in furtherance of the administration of justice, national defense, or national security,” even if that damage does not result in provable loss over \$5,000. Under previous law, first-time offenders who violate section 1030(a)(5) could be punished by no more than five years’ imprisonment, while repeat offenders could receive up to ten years. It was argued, however, that this five-year maximum did not adequately take into account the seriousness of their crimes. In addition, previous law set a mandatory sentencing guidelines minimum of six months imprisonment for any violation of section 1030(a)(5), as well as for violations of section 1030(a)(4). Section 814 raises the maximum penalty for violations arising out of damage to protected computers to ten years for first offenders, and twenty years for repeat offenders. Congress also chose to eliminate all mandatory minimum guidelines sentencing for section 1030 violations. New legislation has also been introduced to further increase these penalties (Milone, 2013).

IMPLICATIONS FOR THE CRIMINAL JUSTICE SYSTEM

Law enforcement agencies and their processes play a pivotal role in criminal justice systems’ overall goal of controlling crimes and imposing penalties on those violating laws. Their important work is the catalyst for the involvement of subsequent system components. Central to the duties and responsibilities of law enforcement officers is taking reports and investigating crimes, as well as gathering evidence. They are also responsible for protecting evidence, conducting follow-up investigations and are frequently

called upon to give testimony in court proceedings (Concer, Paynich & Gingerich, 2013). At any point during the course of these duties, there are formidable challenges as it relates to Hacktivism. Though there has been some success in the arrest of individual hackers, usually high profile personalities, opportunities yet persist.

The courts also encounter problematic areas. Jurisdictions are often blurred lines that traverse local, state, national and international boundaries. Complications also occur because the world of Hacktivism is populated with thousands of bad actors and groups – often leaderless – amounting to a decentralized network of criminals masquerading as self-proclaimed activists (Denning, 2015). Since it is frequently difficult to identify specific hacking organizations, groups and individuals, criminal justice systems' response to the criminal actions of perpetrators from investigation, prosecution to sentencing, the urgency is all the more real. Time is always of importance, especially given the capriciousness of cyberspace and the lack of perpetrators needing a geographical locale. This significantly impedes efforts to shut them down.

Human and financial resources are key in launching, sustaining and insuring that persistent countermeasures are in place, starting with an effective cybersecurity workforce. Disturbingly, the current availability level of cybersecurity professionals is not meeting today's market demands (Perhach, 2018). When these systems fail, criminal justice networks will require an unprecedented amount of technological advantages at their disposal to adequately investigate and prosecute cybercriminals operating under the guise of hacktivists. Cooperation among federal and international jurisdictions is often warranted. This will occur when damages are significant, established cybercrime laws have been violated and there is a mutual agreement among countries.

CHALLENGES TO PREVENT HACKING

As challenging as hacktivist attacks are, they can be met if the United States and like-minded countries undertake the awesome tasks to do so. The first step would be to organize properly, working across national jurisdictions to ensure the stability of the global internet system. An international cyber strategy made up of capable nations consisting initially of the United States, and others could join together to create international standards, protect infrastructures and undertake common approaches to develop a more resilient future internet. Such an approach could both go far beyond what current institutions can do independently, but also build on and make enforceable standards and other actions undertaken by other entities. The key is combined efforts by like-minded stakeholders across international borders, rather than reliance on narrowly focused groups from one or a few countries – an approach which has been a miserable failure (Klein, 2015).

Hacktivism has become an integral part of modern life, and modern institutions are necessary to safeguard it. It has the obvious characteristic of simultaneous maneuvers across multiple nationwide boundaries, with the potential of creating universal impacts. An international cyber strategy would work best by focusing on three areas. First, it could protect the critical infrastructure backbone of the internet – those entities that are systemically important to internet stability. Second, it could establish an enforceable set of standards for the rapidly emerging so-called “internet of things,” which is now inclusive of a range of consumer household products. An example of this is the blue tooth technology used for cell phones. Third, the national members tasked with developing the strategy would have all been subject to Hacktivism, cyber espionage, politically motivated intrusions, and criminal activity. The strategy then could help coordinate international responses to these activities, including the sharing of data, analysis and tools, and undertaking coordinated campaigns and responses (Klein, 2015).

RECOMMENDATIONS

The following directional recommendations for scholars and practitioners are important steps in making sure that Hacktivism remains at the center of emerging criminal justice issues needing to be addressed through research. Further, it is an issue that must be incorporated across all landscapes, from the classroom and professional conferences to the more complex process of lawmaking. The study of Hacktivism has a future in political science and in social science more broadly. This indicates that researchers must fully conceptualize the range of issues that conforms to Hacktivism's peculiar characteristics, and make it a useful laboratory for addressing certain kinds of social scientific inquiries. Contemporary conclusions about Hacktivism are by necessity more speculative.

There are two countervailing forces that are interacting to shape Hacktivism's future: first, the post September 11, 2001 terrorist attacks against the United States (9/11) security environment, and second, the expanding domain of international political affairs. The events of the 9/11 changed the context for Hacktivism in two crucial ways. First, they increased U.S. vigilance towards all potential security threats, including cyberterrorism. Second, the immediate and longer-term political consequences of 9/11 have led to the deepening of various international conflicts implicated in international Hacktivism (Milone, 2002). Increased vigilance against the prospect of cyberterrorism has had its most tangible impact in the increased penalties for all forms of computer hacking – potentially including much of hacktivist activity. Though the USA PATRIOT Act amended the Computer Fraud and Abuse Act (CFAA) to lower jurisdictional hurdles relating to protected computers and damages, and increase penalties for violations (Milone, 2002), additional research should be conducted to ensure that legislative and regulatory mandates are available and consistent with both state and federal laws.

CONCLUSION

The lens in which to properly view Hacktivism must be all encompassing to include a global perspective of cybercrimes. Also, the full range of noted and potential threats against targeted political elections, industry and corporations, international affairs, personal data, and national security are rapidly increasing and evolving. Further, this rise in criminal behavior uniquely positions criminal justice systems to reinvent how they research, investigate, and hold offenders accountable. Systems are beyond the proverbial “crossroad” regarding Hacktivism; rather, they are in the middle of an important battle. Leadership must be from the front of this issue, not the back. It is within the capacity of well-balanced, financed, and resourced collaborations to do more. Effectively countering Hacktivism rests with eradicating two basic, yet flawed ideological assumptions. First, this is complex work – there is nothing simple or easy regarding the levels of human and technological resources needed to launch credible and sustained proactive, as well as reactive responses. Second, as previously noted, this is a network, therefore a formidable and equally robust response from local, state, regional, national and international network must be activated. The levels of cooperation among all stakeholders must be unprecedented. Equally, aggressive levels of human and technological resources must be ensured and not be prohibitive. From perhaps well-meaning protest activities perpetrated via the internet to obvious violations of laws, Hacktivism is the new intractable imperative for criminal justice systems.

KEY TERMS AND DEFINITIONS

Activism: A strategy implementing a form of forceful demonstration in order to bring about partisan or societal transformation.

Computer Fraud and Abuse Act: This 1986 Act serves as a modification to existing laws seeking to address issues of deception within the cyber realm. Computer users must receive proper authorization and must not exceed boundaries of authorization.

Criminal Justice System: A system inclusive of law enforcement, the courts, and correctional practices established to control crime and penalize violators.

Cybercrime: Illegal actions conducted via any technological device, which includes hardware and software.

Hacker Culture: A subculture of individuals who abuse vulnerabilities in systems for a common goal.

Hacker Ethics: Principles and ideologies that are shared in hacker culture.

Hacking: Manipulation of a technological device to acquire data unlawfully within a system.

Hacktivism: The combination of ‘hack’ and ‘activism’ to explain the use of technology in the promotion of political or social change.

USA Patriot Act: The Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 which granted the federal government increased control in monitoring and interrupting networks in order to counterbalance terrorist attacks.

Hacktivism and Alternative Journalism: The Case of the French YouTube Channel Thinkerview

2

Stockholm University, Sweden

INTRODUCTION

At the end of 2012, a new YouTube channel named *Thinkerview* was created in France. This channel only contains interviews, between guests and a journalist who does not appear in front of the camera. The frequency of these interviews notably increased between 2013 and 2018. As of 30 November 2018, 126 interviews had been recorded and posted, with durations of between 16 and 140 minutes. The existence of such channels was made possible because of the creation of the YouTube platform in February 2005 (Jarboe, 2011, p. 2), a platform that allowed people to create and edit videos, and make content available immediately, online (Burgess, Green, 2018). Furthermore, it is possible to archive and show old interviews on the platform, thus creating a historical background, which is necessary in order to show a long-term perspective¹. By means of self-generated YouTube channels, new media actors have emerged on the scene, regularly publishing content (Al Nashmi et al. 2017, p. 169 ; Bärthl, 2018, p. 30). *Thinkerview* describes itself as a web channel designed to establish a new model of interviewing. Thinkerview's self-description refers many times to the existence of a "community", as if there is an "anonymous collectivity" (Castoriadis, 1975, p. 433) that supports the programmes and proposes the questions addressed to the guests.

This chapter analyses the positioning and format of a channel that claims to have a close relationship with, and to represent, hacktivists. Here, hacktivism is not seen as a form of criminal manipulation, but rather as referring to the hacker culture, within which people share information and promote full transparency. At the same time, hackers are people who have strong computer skills, and understand the script sources of the Internet (Frichot et al., 2014, p. 8). The interviews are conducted with people who were engaged in sensitive matters, such as the intelligence services, security, hacktivism, investigative journalism, criminal justice, and geopolitics. Lawyers, journalists, and former French Senior Defence staff have been interviewed, and they've provided details about their fields of experience.

What are the characteristics of the YouTube channel *Thinkerview* that distinguish it from classical media in France? In order to describe the work of that channel, it is important to use the concept of Critical Discourse Analysis (henceforth CDA), that focuses on the interactions between the *medium*, the actors, and the scenography. In other words, CDA does not limit itself to the words pronounced by the actors, but analyses the context and social position of the actors. The scenography is also very important, as it creates a specific atmosphere. Scenography is a word borrowed from the theatre, that focuses on performance: "Exploiting the physical power of the performer in the space can illuminate the text, especially if the performers feel confident that they are the primary storytellers" (Howard, 2009, p. 33).

DOI: 10.4018/978-1-5225-9715-5.ch023

In analysing scenography, it is important to focus on the concrete details, such as the construction of the interview, its announcement, and the preparation of the guest. The guests have up to two hours to answer all kinds of questions regarding their jobs, salaries, activism, and political and philosophical backgrounds. Our hypothesis here is that this channel institutionalizes a new critical medium, offering another perspective on the current situation. Thus, these channels can be seen as a form of alternative journalism (Atton, Hamilton, 2008, p. 123), with the aim of uncovering and exposing aspects of contemporary reality that are not covered by classical media. The channels give a voice to investigative journalism and critical thinking, in order to question the dominating discourses. This chapter analyses this “posture” (Panier, 2008, p. 73), in order to see whether the interactions between the guests and the journalist tend to develop a critical discourse on the methods of conducting journalism (Peters, Broersma, 2013). CDA is useful here, as it offers a critical approach to a discourse that pretends to be critical. Hence, it is important to question whether the characteristics of this channel fit its initial intentions.

BACKGROUND

Hactivism is often associated with a form of counterpower, where people get access to secret information. Hacktivists advocate for free access to information and data; they were behind the promotion of free software that does not depend on corporate interests (Krapp, 2011, p. 27). They sometimes denounce the manipulation of information, and propose a new process for evaluating facts and information (Coleman, 2014). A hacktivist is a person who does not accept the expansion of the surveillance society, and who fights for the truth even if this posture contradicts the principles of the State. From the point of view of the security forces, a hacktivist can be a spy, who tries to get access to hidden information while serving the interests of a political power (Guldikova, Santagati, 2000, p. 40). According to Taylor, there was an evolution from hacking activities to hactivism, “an activity that began in the mid-1990s and which refers to the combination of computer-hacking techniques with the real-world, political-activist ethos of new social movements, DIY [Do It Yourself] culture, and anti-globalization protests” (Taylor, 2004, p. 486). Numerous studies have also focused on the instability of cyberspace (Lucas, 2016, p. 17), and the possibilities of manipulating information (Bidgoli, 2009).

At the same time, a hacktivist is also someone who can troll and use non-conventional actions that are criminal (Goode, 2015: 76). The issue of hackers is innately related to cybersecurity issues; hackers are always anonymous, and the frontier between good and bad hackers depends on the context. “More particularly, the hacker community, which forms a strong part of the hacktivist community, is intrinsically linked to the resistance-facilitating potential of technology, challenging established operational and behavioural standards” (Karagiannopoulos, 2018, p. 7). In other words, hactivism is linked with a radical form of freedom of expression, and illustrates a form of electronic civil disobedience (Karagiannopoulos, 2018, p. 49; O’Malley, 2013, p. 140). There can then be a juridical difficulty in determining whether a hacktivist community is simply an outlaw group with illegal behaviours, or whether they are only trying to enlighten the people’s critical thinking. This ambiguity is challenging, as hackers can perceive themselves to be electronic secret agents (Webber, Yip, 2018).

CDA has an interesting perspective, as it focuses on the methodology, rather than on a set of methods. “Settling on a methodology for a particular research project is not just a matter of selecting from an existing repertoire of methods. It is a theoretical process which constructs an *object of research* (a researchable object, a set of researchable questions) for the research topic by bringing to bear on it relevant theoretical perspectives and frameworks” (Fairclough, 2010, p. 225).

MAIN FOCUS OF THE ARTICLE

From this perspective, it is relevant to study the channel *Thinkerview*, a channel that aims to offer enough time for the interviews to tackle all kinds of issues. The selection of the guests, and the scenography, is important, as the performance is presented without any reconstruction. The YouTube channel provides the possibility of following and reacting in real time, but it also allows the interviews to be archived, and provides proof of the popularity of the channel with direct statistics (Kiernan, 2018). The real time effect is all the more interesting, as it creates a form of spontaneity with anecdotes, private jokes, or other details that are usually suppressed in other broadcasts.

THE PROFILE OF THE GUESTS

Statistics on the Interviews

The selection of guests is, of course, the key-concept, as they will be at the centre of the interview. The channel consists of 126 interviews, conducted between January 2013, and 10 December 2018; on occasion, interviews are conducted with several people at the same time, but there is always a hidden journalist guiding the discussions. In total, 171 people interacted with this journalist during these five years, but the number of interviews increased in 2017 and 2018. 46 interviews were conducted between 2013 and the end of 2016, which means that around 64% of the interviews were held in 2017 and 2018². This shows that the channel established logistical routines, and developed a model of interactions that was tested during its first years. In terms of average views on YouTube for each interview, there are around 128,933 views per interview, but the channel's popularity increased from 2017 on, as the average views between 2013 and 2016 were 92,180³. Table 1 presents the main characteristics of the channel.

The gender variable is noticeable, as women constitute only 10% of the interview subjects, as if to say that expertise and knowledge of the world are reserved for men. The gender perspective is not considered by the channel, and feminist issues will not be tackled here as a specific and relevant topic of investigation.

It seems that there is a desire to collaborate with other networks, sharing the ideology of the channel, possessing expertise in domains that are close to the channel's concerns. *Thinkerview's* homepage states, "ThinkerView is an independent group on the Internet, and is very different from most of the think tanks that depend on political parties or private interests"⁴. There is also a quote from Marc Ullmann (1930-2014), a former journalist and essayist who proposed concrete solutions for addressing crises (Ullmann, 1994). The channel presents itself as a tribute to Marc Ullmann; the objectives are then listed as the following: "Test the ideas / discourses by discovering their flaws, their limits. Listen to alternative points of view, in order to broaden our interpretation of reality. Understand the complexity of current and future issues in our world"⁵. The economic model of the channel is crowdfunding, using the platform

Table 1. Characteristics of the channel (2013-2018)

Number of interviews (2013-2018)	Number of individuals interacting with the journalist (2013-2018)	Average number of screen views (2013-2018)	Average duration of each interview (2013-2018)
126	171	128.933	76 minutes

Source: own analysis

Tipeee to avoid any form of dependence (Renault, Ingarao, 2018: 200). Other partners are visible on the page before each interview, they are korben.info, Hashtable (h16free.com), Les Éconoclastes, www.lareleveetlapeste.fr, yogosha.com, sikana.tv, hashtable, yeswehack.com, sixtine.com, lescris.es.fr and captainfact.io. These networks share the same characteristics, as the main authors are anonymous, such as with Hashtable (h16free.com). H16 also published works that focus on current ideologies on climate change. “Maybe I’m going to scare you, but I’m not sure if the information has come to you, I’d like to let you know; given the current situation, the planet is in a bad state, and we’re all going to starve” (H16, 2015, p. 1). H16 is a hacktivist who promotes critical thinking and autonomy. Lareleveetlapeste.fr is an independent publishing house, and a media player. “We are a 100% independent publishing house and media player that self-finance in total autonomy. Our scope is humanist, ecological, and especially antiracist. We finance ourselves with the sales of our books”⁶. This network of partners is cautiously chosen, in order to avoid any kind of dependence, and it is regularly updated. For instance, in the first picture of the interviews from 2017, the partners sikana.tv and captainfact.io did not appear; the network of partners was not large then. The extension of the network of partners afterwards reveals that critical and independent media are encouraged and promoted by *Thinkerview*. Sometimes, during an interview, the journalist asks the community to check some facts on the Internet, to support the discussion. This kind of interaction is very important, in order to avoid misstating facts. In other words, it helps to promote critical thinking as a distinctive feature. The opposition between small circles of people who understand geopolitical issues, and the mass of consumers, is often mentioned in the interviews, such as the one with Pablo Servigne, who promotes concepts such as degrowth⁷.

Networks of Expertise

The guests are invited by the journalist, who uses the alias “Sky”, through his network of contacts. Some guests are recurrent, as the networks allow the journalists of *Thinkerview* to select some favourite guests, such as Pierre Conesa⁸, Alain Juillet⁹, and Olivier Delamarche¹⁰. The association *Les économistes éconoclastes* has also recently started to collaborate with *Thinkerview*. It seems that most guests are people with current or previous experience in domains such as National Defence, Journalism, Finance, Law, Climate change, Astrophysics, or digital issues. The channel has also invited several guests from the army, the intelligence services, and the police. The channel tries to offer an equal voice both to people who fight against mass surveillance procedures, and to people who oppose them on security issues. The case of Alain Juillet is interesting here, as he was a former intelligence agent, and he uses his expertise to explain how the intelligence services contribute to geopolitical relations. The channel is extremely interested in these topics. In the present chapter, the hidden journalist is referred to with the letter J, while the guest is indicated by the letter G. “J: We are going to discuss geopolitics, terrorism, finance, and maybe a little bit about hacking”¹¹. The guests that have expertise feel at ease when they talk about different topics. “J: We begin with Russia; would you be interested in that topic? G: That is a very interesting country, especially with what is going on now, no doubt. J: The Skripal affair, can you say a few words about it? What is your point of view? Is it Cold War propaganda? Do the Russians have something to reproach themselves for? Can you be our spearhead G: The Skripal affair, yes, first of all, it is true that it is...it is an operation that reminds us of the Cold War”¹². The use of ellipsis is worth noticing here, as it is not the country in and of itself that is interesting, but the current situation and the role of Russia in geopolitics. Even in the presentation, the interaction between the expert and the journalist reveals a common interest in describing the geopolitical situation of Russia. This is concrete proof that *Thinkerview* was able to commence its activities thanks to strong networks of expertise (McClurg, 2003).

Favourite Topics or “Killing Darlings”

It is possible to identify several recurrent topics throughout the different interviews. These topics are: geopolitics; security issues; climate change; environmental issues; and the core idea, that of a coming collapse of capitalist societies. The channel promotes different thinkers, and at the end of each interview, the journalist always asks for three books that the guest would highly recommend for a better understanding of the evolution of the world. The agenda is to invite guests, from different ideological horizons, that can discuss the ideology of collapsology. The journalist of *Thinkerview* refers several times to the whistle-blower Michael Ruppert, who predicted the end of economic growth, and a major threat to humankind. Michael Ruppert died a few years ago, and the journalist pays tribute to his documentary on collapse and degrowth¹³. Other distinguished guests share those ideas. For instance, Pablo Servigne, a former engineer who devotes himself to studying the effects of climate change, strongly echoes the idea that collapse is unavoidable. He claims that, unfortunately, most citizens and institutional powers deny this reality, as it would imply changing the economic model of consumption that is based on false ideas of growth. Curiously, other distinguished guests, such as Olivier Delamarche and Charles Gave¹⁴, who are more liberal, also express similar concerns regarding a collapsing financial system. Their main idea is that the European economy is dependent on debt, and that the production of financial liquidity is an immediate reflex of the so-called bureaucrats. These economists belong to very specific networks, such as the *éconoclastes* who cooperate with the *Thinkerview* to organize talks. Some distinguished guests were invited to regularly express their thoughts on geopolitics, such as Pierre Conesa, a former high official from the Department of Defence. As examples, Pierre Conesa shared his expertise on the evolution of Saudi Arabia, on diplomatic relations between France and Russia, and on the war propaganda that we are subjected to (Conesa, 2018).

These guests also have expertise on a dissent discourse regarding the evolution of economic and political institutions in France. *Thinkerview* has also invited some well-known lecturers, such as Jean-Marc Jancovici to talk about the energy crisis, or Bernard Stiegler to discuss the disruption of social links. Jean-Marc Jancovici is an independent lecturer, in the field of energy resources, who has won a large audience for himself. His main thesis is that it is of the utmost priority to invest in decarbonized energy¹⁵. “J: What are the risks, do you think that there is a threat, mmh, that the population is exposed to threats? G: I will begin by not answering your question, and finishing what I previously began with, the only way for me to explain the topic is to use different contact persons [...] If I succeed in convincing a trade unionist, big company executive, or a representative of the economic sector, that my topic is, on the whole, something good for him, then I’ve made a step forward, as he will be able to diffuse a more convincing discourse”¹⁶. Jean-Marc Jancovici thus revealed his lobbying strategy for getting his topic on the agenda. *Thinkerview*’s role is to promote these topics, such as social vulnerability to climate change, and economic collapse and its consequences. As for Bernard Stiegler, he is a philosopher who has devoted his life to studying technological changes (Stiegler, 2018). He has also criticized the development of digital technologies, as he feels they entail the risk of accelerating the destructive forces of the market ideology¹⁷. Here again, the presentation empathizes with the critical role of the guest. “Good evening, Bernard Stiegler, we welcome you to an Internet channel called *Thinkerview*, we are on the air, we welcome you because you are a philosopher, and we noticed that you were deeply interested in topics that we have been discussing for several years, such as the economy, the media, and many other things, including education and, especially, the Internet. How are you doing?”¹⁸

Even if the journalist begins with topics corresponding more with global fields, the strategy is to let the guest talk, and then to ask specific questions regarding the topics, and solutions. Then, Bernard Stiegler continued with a reflection on the American media, and Hollywood, as a machine of desire that produces an idealization of values. He then went on to make a distinction between drives and desires. “Freud explains that to transform drives into desires, it is necessary to educate and transmit a process that operates between the child and his family”¹⁹. The idea was to show that cultural industries destroy the socialization process, and that it is even worse with the digital revolution, as it reduces the possibility of concrete interactions. If the maturation process from drives to desires is broken, there is a risk of devolving to a more primitive state, where individuals do not cooperate. Bernard Stiegler, through his interest in digital objects, thus addressed a critical point of view on the process of civilization. To some extent, he fits in the framework of collapse theory, the main focus of the channel. The questions, therefore, lead the guest to discussing this favourite topic (Nichols et alia, 2010).

The question of digital matters is also one of the expertise zones of *Thinkerview*. The channel invited the current Minister for Digital Affairs²⁰, Mounir Mahjoubi, to talk about how the government is preparing for the digital transition. They always try to invite guests that do not share the same viewpoint on a topic, and this is also the case in regard to attitudes concerning artificial intelligence. For instance, they invited one of the promoters of artificial intelligence, Laurent Alexandre²¹, and a critical voice in the person of Éric Sadin²², a philosopher who presents himself as a strong opponent of the concept of transhumanism. Transhumanism is the belief that, with the development of artificial intelligence, human beings will become a mixture of organic and digital components. In other words, transhumanism puts emphasis on the improvement of human faculties with these technologies. Éric Sadin, for his part, rejects this ideology, which he considers a neoliberal derivative that will model a human being in a very conformist manner. Here, the journalist interrupts guests in a very critical way, when he addresses the questions extracted from the community’s reactions. The confrontation between guests (Éric Sadin opposed Laurent Alexandre, who does not have legitimacy in the field) activates an interaction between all the interviews. It creates a continuity and a historical background, and shows that the channel has the capacity to invite people from opposing ideological backgrounds. One of the characteristics of *Thinkerview* is its ability to take enough time with all its guests in order to deepen the diversity of critical points of view. From this perspective, the scenography is worth studying, in order to analyse how the guests are prepared for the interviews.

THE EFFECTS OF THE SCENOGRAPHY

There is a link between the CDA and the conversational analysis. The conversational analysis focuses on small details (gestures, smiles, interruptions, recurrent interactions), and is illuminating when studying how the guests are prepared, and how they interact with the hidden journalist (Garfinkel, 2002). The aim, here, is to look closely at details that do not seem very interesting at first, but which can offer further insight on our topic. Thus, framing is relevant here, when analysing the interaction between the guest and the journalist in the studio (Goffman, 1966). Language is also used in a very pragmatic way when discussing challenges and solutions to very sensitive problems.

The journalist is behind the camera; he asks questions, makes comments, and reads some questions from the audience that were sent online via social media. The forum on YouTube is used to increase the interaction with the audience. The music played over the opening credits is an intrinsic part of the inter-

view; it can often go on playing for a few minutes until the guest arrives. The music was commented on several times in the channel's forum²³. One of the subscribers wrote the following remark: "When I hear the first notes, I feel transported; I say we will change the world". Another subscriber replied by saying "We will change the world, we are already changing it"²⁴. The music introduces a sense of drama, before the guest comes on the air. The interview is presented as focusing on the performance of the guest, as he or she answers the journalist's questions regarding different topics that are important for the channel.

Presentation of the Channel

The channel's logo is a black swan, which is employed as a symbol of critical thinking, and refers to a theory in statistics regarding the probability of events. Nassim Nicholas Taleb, a writer and PhD in Economics, recently developed this theory. The premise of it is that there is a distance between the reaction of surprise to an event, its consequences, and the reconstructions of its meaning afterwards (Taleb, 2018, pp.1–5). The logo thus possesses a visual identity closely related to the main message claimed by the channel; there is also an anarchistic connotation to the black swan, which is associated with hacktivist values. The engaged hacktivist is believed to be able to predict events in the unfolding crisis of Western societies.

The presentation of the channel is always the same after the opening credits and music case. The journalist introduces the channel, and offers the floor to the guest, so that he or she can describe their activities. The interaction with the guest arouses the attention of the audience. The following example illustrates the sorts of effects that the interaction produces. This is a simpler transcription of conversation analysis (Have, 2007, p. 95) for the forthcoming sequences. "J: Good evening Jérémy Ferrari / G: Good evening / J: We are on the air; can you briefly introduce yourself? / G: Well, my name is Jérémy Ferrari, indeed, I am a humourist and I am on the air (smile) on Sky News / J: On? / G: On Sky News, right? / J: on Thinkerview / G: Thinkerview, Ok, I thought it was more megalomaniac / J: No, no, no, we are a team, we are not megalomaniac; we put our egos aside"²⁵. Here, the interaction is very interesting, as the humourist tries to mock the name of the channel, but at the same time, he does not seem to know its real name. This quick interaction contributes to a better presentation of the channel, even though the journalist goes on with the curriculum vitae of the guest. There is a switch of postures as the guest interrupts the hidden journalist, in order to make him talk about the channel and the objectives. The last sentence ("We put our egos aside") closes the discussion, and the focus shifts to the profile and interests of the guests. Jérémy Ferrari is the second humourist that the channel invited on the air, after Guillaume Meurice in 2017. The presentation of the guest is a part of the scenography, as the journalist justifies the choice of the guest. In the interview with the expert Jean-Marc Jancovici, the main idea was to provide him a voice so that he could put pressure on citizens and political elites: We would like to have your ideas, your opinions on what is going on, the energy, the climate, the carbon tax, all of these small topics (G smiles); how are you doing? G: Well, I am still alive; this is a beginning (G smiles). J: How is it going with your work; is the population sensitive to what you say on the Internet? J: It depends on how we measure the sensitivity."²⁶.

The audience knows that the debate will have some scientific resonance, and the expert is legitimized because he has an unconventional approach to the topic. The question "How are you doing?" is interesting, as most of the guests answer "Not so bad", to illustrate the dramatization of the topics, and the global questions that are dealt with during the interviews. There is a pragmatic intention here, as the

guest expresses how he feels in connection with the topic that will be treated. For instance, Jean-Marc Jancovici's focus is on his message, and how he tries to alert people about the consequences of an over-addiction to some energy sources, such as carbon. Jancovici's concerns are presented as being directly connected to the *repertoire* of *Thinkerview*. This does not mean that the channel approves of his point of view, but it appreciates the critical focus of the guest.

The Analysis of the Backstage

The hidden journalist can sometimes interact in a very relaxed and familiar way with the guest, as was the case with the journalist Isabelle Saporta on 13 March, 2018. Isabelle Saporta has a PhD in Political Science, and she is a journalist and a writer. She began the interview by commenting on what happened before the interview, and how *Thinkerview* contacted her. "J: Good evening, Isabelle Saporta / G: Good evening / J: We welcome you today to a web channel called *Thinkerview*; we welcome you because you are an expert journalist on topics such as agriculture and health; how are you doing? / G: Well, not too bad, in fact, it feels good to be here, I feel pretty good / J: Why "in fact"? / G: Because you are strange, you contacted us in a weird way, didn't you? The phone call was weird, but I liked it; you had to have an instinctive feeling to know that it was going to be OK"²⁷. The guest was referring to the preliminary negotiations conducted before she agreed to come to the channel's studio. She underlined the direct manner the journalist uses to contact potential guests. Sometimes, during the interview, she alluded to details that aren't relevant to the interview. For example, she told the journalist that she forgot to switch off her mobile phone and, when it started vibrating during the interview, she reacted without the audience seeing it. "G: No, no, it is not my daughter (laugh) / J: Here, we have the name of her lover (laugh) / J: Be careful guys, do not let anyone have access to your mobile. G: Are you sure that I do not have to answer; I have to answer, don't I?"²⁸. The mobile phone is useful as a tool for activating the interaction between the journalist and the guest. These spontaneous interactions create a feeling of proximity between the journalist and the guest, as if the guest has accepted the rules of the game, with the possibility of answering or not answering specific questions. It is for this reason that, in the CDA, conversational analysis is adapted to study the digressions and details that appear to be trivial in the interview. Catherine Kerbrat-Orecchioni has studied the creative processes of interactions that occur during a conversation (Kerbrat-Orecchioni, 2005).

During an interview with the pan-African activist Kémi Séba²⁹, the journalist asked the guest to answer a question while he went to the restroom. This received many comments in the YouTube forum. Such a manoeuvre can disrupt the atmosphere, but at the same time, it allows the journalist to change the focus to another question. Kémi Séba is largely regarded as a radical, but his interview reveals a deep concern for the future of Africa. On social networks such as Twitter, many comments were positive, and people were impressed to have the opportunity to get a theoretical background on African issues. For instance, the account "Numidia" (@AmarHaragaa, 27 November 2018) directly commented on the interview: "I just saw the last interview with Kemi Seba by Thinkerview; I thought for a long time that his aggressiveness was bad for his discourse, but it is just amazing here, thoughtful and with such a deep speech"³⁰. Kémi Séba also reacted to the journalist when his enemy's name, Louis Magloire Keumayou, came up. The interview becomes really interesting here, as Kémi Séba performs a sort of multitasking, as he answers the comments of Louis Magloire Keumayou, who was interviewed by *Thinkerview* on 13 September, 2018³¹. Kémi Séba even directly answered a comment posted by Louis Magloire Keumayou on his Facebook page. The multitasking interaction seems to be a characteristic of the channel. The idea is to reveal all sides of the guest, so that they can show who they are in different situations. Implied in

that premise is that a guest thinks that they have the right to discuss a critical topic that others do not have. The quest for legitimacy surrounds non-conventional topics, as if the interlocutors are outsiders who must cultivate an unconventional positioning. There is an emerging hacktivist *ethos* here, where the mainstream media and common topics are denounced as forms of propaganda dominated by a politically correct style.

THE PROMOTION OF A HACKTIVIST *ETHOS*

One of the favourite topics of the channel is the necessity of having an independent media that acts with professionalism and ethics. The journalist often quotes from the Declaration of Munich, which defined the principles of journalism. The interviews can be opportunities to test the guests on their knowledge of this document, which is perceived as an essential part of the duties and rights of journalists. Six journalist syndicates, in six countries of the European community, signed the Declaration of Munich on 23 and 24 November, 1971. In listening to several interviews, it seems as if the channel wishes to consecrate those principles, especially the first one: “Respecting the truth no matter what consequences it may bring about to [the journalist] and this is because the right of the public is to know the truth”³². For the hidden journalist, the Declaration of Munich is a fundamental text that illustrates the duties of journalists. It explains why the journalist of *Thinkerview* invites other alternative journalists and whistle-blowers onto his programme.

The channel aims at confronting *ethos*, a word that denotes a specific posture in the public debate (Charaudeau, 2017). There is a difference, then, between a prior *ethos* (Amossy, 2010, p. 51), and a discursive *ethos* (Amossy, 2010, p. 75). The prior *ethos* reflects the image of the guest before the interview, in other words, their reputation and what is written about them. The discursive *ethos* reflects the performance of the guest, as he or she tries to react to and correct the prior *ethos*. The focus is on the guest, but at the same time, they are reacting to the expressions of the hidden journalist, and sometimes, there is an interaction with the concrete objects present in the studio. The introductory moments that do not seem important as to the quality of the discussion are, in fact, very interesting, as a deal is made between the guest and the journalist. The guest knows the rules of the game, and agrees to enter into this unconventional interview. Catherine Kerbrat-Orecchioni often mentions the interlocution when the speakers interact and exchange views on a topic (Kerbrat-Orecchioni, 1986, p. 10).

“J: Good morning, Laurent Alexandre, thank you for coming to us in Saint-Denis; we begin when you are done with your businessman’s iPhone (G is looking at his iPhone); we are on the air, we would like to correct something about your background. You are not somebody who demands 5,000 euros for conferences; we tested that; you are very accessible on weekends, and you take the time to come from Brussels to Saint-Denis in order to talk with a community of volunteer hackers”³³. In the scenography, the guest is presented as an important person in the field of artificial intelligence, and the journalist begins by nuancing the reputation of the guest. At the same time, he reveals that the studio is in Saint-Denis, and reminds listeners that the people working with *Thinkerview* are volunteers. Laurent Alexandre does not necessarily react to what is said about him; he knows that he is criticized because he advocates more research into artificial intelligence. The discursive *ethos* aims at confirming the prior *ethos*, which means that Laurent Alexandre can declare why it is important to work on those topics. He positions himself on the scene by distinguishing between the people who imagine a nice future, where human beings can be like gods thanks to artificial intelligence, and those who are pessimistic³⁴. “G: We are going to be in an economic, political, social, intellectual mess; we will have great difficulties in seeing where we are

going; we are in a big fog, and many people have certainties that will be contradicted”³⁵. In fact, in the first part of the interview, the journalist comes back to the social perception of the guest; he acts as an investigator who has extracted information from different sources to paint a mental picture of the guest. There is a prior *ethos* that exists in the public space, and on the Internet, but the journalist redefines this *ethos* before allowing the guests to introduce themselves.

In other words, the typical sequence is the following: prior *ethos* / presentation of the journalist / discursive *ethos*. The confrontation of images is a significant part of those interviews, as the idea is to produce a more nuanced image of the guest. The guests do not really identify with the given prior *ethos*; they are able to show, over the course of one hour, how they think and react. The construction of a new *ethos* illustrates a hactivist posture, where people continuously have to question sources, facts, and news. This channel aims to prevent the development of fake news³⁶, which is why alternative journalism is perceived as having a constantly critical attitude.

SOLUTIONS AND RECOMMENDATIONS

- Analyse the background of the YouTube channel to see if there is a regular structure in regard to the information.
- Investigate the scenography to study what the guest wants to say, and how they are guided through the interaction.
- Compare the prior *ethos* in order to the discursive *ethos* to see how the guest perceives their role in the public debate.
- Describe the occasions where the community is referred to, in order to study who follows up the channel.
- Focus on the topics to see whether the alternative point of view is simple due to a form of radicality.
- Integrate a critical forum where facts, sources and news are evaluated. Hactivist channels can contribute to a better critical analysis of media.
- Use long interviews with no montages in order to create an atmosphere of authenticity.
- Produce a critical image of the guest by giving them time to develop their point of view.

FUTURE RESEARCH DIRECTIONS

The objective was to study all so-called alternative media in order to see how they perceive their role, and what types of interviews are prioritized and selected. The combination of CDA and conversation analysis is useful in this, as it is possible to compare the prior and discursive *ethos* that emerges in these kinds of interactions. This research is all the more important, as these small details reveal the objectives and methods of hactivists who reject traditional media. Furthermore, research should be conducted into media that promote alternative facts, or a critical point of view in different fields. Who are the guests? Why are they invited? What does the audience know about their background? A focus on interactions without any montages could be an opportunity to see whether the corrective *ethos* emerges in such a configuration.

The topics of such channels could be studied in detail to see whether the guests bring alternative facts, or a critical point of view on a current debate.

CONCLUSION

2

The channel *Thinkerview* has a central diagnosis on the collapse of the capitalist model of society, and aims to reinforce critical thinking about facts, sources, and interpretations. It invites guests who have a critical point of view, and thus who are not necessarily recognized in the classic media, to appear, even though other official guests can be invited. It is easy to point out the interviews where the hidden journalist shares a form of empathy with the topic. On the whole, the channel attempts to redefine the task of journalism, which is based on critical thinking, independence, and investigation. The ideological references from the journalist are quite obvious when it comes to environmental issues, financial matters, or a mistrust of the classical political establishment. The level of expertise can be quite high, as some scientists are invited to expound on, for example, a novel theory on astrophysics. The objective is to make the channel look like a sort of open university, where it is possible to learn more and check the facts while a distinguished guest talks. The interaction with the anonymous community is quite interesting, as the channel perceives itself as a legitimate medium for critical people. There is a mutual idealization of the channel and the community, as the channel describes a well-informed community, whereas the channel is seen as an alternative mode of information by the majority of subscribers, when the commentaries are analysed.

The ideological part is not the most important one, as the scenography only focuses on the answers and the attitudes of the guests. Long interviews with questions that are not anticipated seem to be the rule; the model of *Thinkerview* has improved in 2017 and 2018, with a larger number of subscribers. The analysis of the attitudes of the guests reveals that the interview confronts, in a systematic way, a prior *ethos* with a discursive *ethos*. In other words, the guests have the opportunity to build a new *ethos*, depending on how they develop their answers. The channel aims to reinforce the links between a community of hackers who think critically about controversial issues. It also offers to some anarchist movements the chance to have a wider audience (Collister, 2014, p. 770).

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Artificial intelligence refers to the creation of an intelligence which is different from human intelligence.” by “The creation of an intelligence, different from human intelligence, usually from computers.”

Collapsology: Set of theories that assumes that the Western societies are about to collapse” by “A set of theories that assume Western societies are about to collapse, and that the global crisis.

Conversational Analysis: Study of the frame of the conversation with specific attention paid to interactive details (interruptions, reformulations).

Critical Discourse Analysis: Field of research that compares the social role of the speakers and the scene of enunciation.

Discursive Ethos: Image of the self that appears during an interview or a discussion.

Hactivism: Political engagement around hacking activities and the access to free and independent information.

Prior Ethos: Image of the self before the discussion (perception of the self by others).

Scenography: Study of the scene frame (concrete location, definition of the setting).

Transhumanism: Ideology that promotes the development of human beings through their interaction with artificial intelligence.

Universidad Nacional de Río Negro, Argentina

INTRODUCTION

The massive expansion of social media networks makes it necessary to study them from an interdisciplinary point of view.

In Argentina, the use of digital social networks led government agencies to share through them public and management information, substantially increasing their presence in these new platforms.

From an administrative point of view, social networks are thought of as tools which facilitate access to public information to the citizens. On the one hand, they give everyone easy access to public information, and, on the other, they shine a light of transparency and effectiveness to the activities of public agencies. These features make them engaging for the members of the administration.

The benefits derived from their use seem clear and numerous. Nevertheless, the actions performed within them produce certain legal conflicts. To be able to use them, you must agree to a contract with pre-established clauses which might a priori override certain principles ruling the Public Administration of Argentina, and of other countries protecting their citizens with data protection acts.

In that respect, this work aims to make a communicational-legal analysis which particularly focuses on how the State uses social networks within the legal framework of Personal Data Protection Acts, and whether it enforces compliance with the law by those entities which have the right to freedom of expression, but are not responsible for protecting the right of privacy of the citizens.

Analyzing the use of Social Networks by State agencies in Argentina from a legal perspective is quite relevant, because of the countless facets deriving from that issue, each of which requiring an individual and detailed analysis. Therefore, and in view of the contractual terms and conditions users accept when using digital platforms, a comprehensive analysis will be made as to the obligation of the State of protecting the citizens' personal data, and the legal framework governing such case.

To that aim, we will analyse the presence of public agencies on the social networks, the information they provide to them, and the potential lack of legal protection of the citizens.

The analytical method is to study certain cases in which public entities have shared information on the networks, while at the same time collecting sensitive information about the citizens. The research variables refer to the publicity of public information and the right of privacy.

The cases chosen were the Facebook pages of the National Agency of Social Security (ANSES, in Spanish), the Government of the City of Buenos Aires, and the Ministry of Education of Argentina.

SOCIAL NETWORKS

2

When we talk about “social networks”, it is important to consider them as a wide concept and a tool with countless facets. Before examining in detail the digital platforms, which enable interactions among users, it should be said that networks are previous to the appearance of digital technologies; that communities, are articulated in a relational manner, that they are centrally based on connections, and that interactions are their fundamental feature.

Passing now to the analysis of platforms, Fernando Tomeo refers to them as “...Internet Sites (digital platforms), which enable users to show their profiles, upload photos, tell personal experiences, chat with friends, and, in general, share and exchange all types of contents (information, opinions, comments, photos, videos)” (Tomeo, 2010) (Own translation).

Then, it should be possible to say that these virtual sites, which are a vehicle to social communication, allow people to share and exchange contents and enter into free relationships with other users, which enable them to connect and interact on the Internet. In this way, we could refer to convergent communities in digital interaction.

To a greater or lesser extent, platforms increase their popularity and their function is no longer reduced to being mere communication channels. Their use may be analysed from many perspectives: from the technical point of view, as to the incalculable amount of information circulating; from the economic point of view, as to the continuous amount of money these data and information generate; from a psycho-social point of view, as to the sense of belonging and omnipresence they create when people engage with other people -known or unknown to them- from around the world, whether on a social, work-related or personal level, among others.

The power and growth of these virtual platforms focuses on the storage of information and personal data. This also enables them to create algorithms to determine the preferences of the users, and to develop specific segmentations based on consumption patterns. (Tomeo, 2012).

The legal relationship between the user and the social network is established through a contract of adhesion. The user agrees to a set of clauses unilaterally established by the company, without having the possibility of negotiating any of the terms and conditions stipulated.

Generally speaking, and specifically in relation to the contractual terms and conditions, most of the social networks have similar clauses. For the purposes of this analysis, we will analyse the terms and conditions laid down by Facebook (Facebook, 2019) and Twitter (Twitter, 2019), since they are the virtual platforms with more presence of official State accounts.

Facebook, for its part, has become the social network with the highest number of users. According to Digital 2019 Global Digital Overview, it has more than 7.77 billion users and 2,200 million daily active users (We Are Social, 2019). That makes of Facebook the most profitable social network in the world, with a market value of more than \$ 400 billion (ElEconomista.com, 2019).

The increasing use and presence of this social network in Argentina has made the company set up Facebook Argentina S.R.L. in 2011, which currently has more than 20 million monthly active users within the country. This number is a clear evidence of how relevant this network has become in Argentina in terms of scope and expansion. Since the number of users accounts for more than half of its population, Argentina is among the 20 countries in the world with the higher number of users, and second in the region after Brazil (Fernandez, 2019).

The power and growth of this virtual platform focuses on the storage of information and personal data. This also enables it to create algorithms to determine the preferences of the users, and to develop specific segmentations based on consumption patterns. (Tomeo, 2014)

By contracting Facebook, a legal bond is established in which the user accepts a contract of adhesion made out of various supplemental documents where the general terms of service are laid out. Some of them are:

- Statement of Rights and Responsibilities of the Users
- Data Policy, which describes the type of information collected by the social network and how that information will be used and shared
- Payment Terms, which lays out the provisions governing payments through the platform.
- Provisions related to Advertising Policies, guidelines applied to Promotions and Brand Resources, Page Terms and Conditions.

Each of these documents is accepted by the user when creating a Facebook account. All it takes is a “click”, and users might not be aware -many times- of the risks entailed.

The Statement of Rights and Responsibilities (SRR), lays down the general guidelines on the use of the data assigned to the virtual platform, licenses granted, legal aspects and applicable jurisdiction.

By accepting the SRR and the supplemental documents, the user:

- Automatically agrees to the clauses laid out on them.
- Gives consent to having his/her personal data transferred to and processed in the United States, according to section 16.1 of the Statement.
- Grants Facebook a worldwide non-exclusive, transferable, sub-licensable and copyright-free license to use any content with intellectual property rights posted on Facebook. The license ends when the content is erased, unless it had been shared with third parties who had not deleted it.
- Provides instructions to report illegal contents, fake profiles or false advertising, which are deleted after previous analysis.
- In relation to intellectual property rights, it must comply with the applicable laws, and more specifically, with the Digital Millennium Copyright Act and the Video Privacy Protection Act of the United States.
- Facebook establishes unilateral limited liability.
- It submits itself to the jurisdiction of the United States District Courts for solving any claim or dispute.

When signing up for Facebook, the user accepts all the above-mentioned clauses and, at first glance, he/she should comply with them without being able to challenge them.

As to Twitter, it is a social network with an important number of followers and it has become another leading social network on the Web, thanks to the users it adds every day, its monetary revenue and its market value. This social network has currently around 326 million users across the world (We Are Social, 2019).

Broadly speaking, Twitter and Facebook have quite similar Privacy Policies and Terms and Conditions, and their contracts do not hold major differences.

The terms of service laid out by Instagram, Snapchat and Youtube are also similar to the ones developed above.

According to the basic principle of contract law, the most relevant clauses of the contract of adhesion to social networks which were mentioned before are legally-binding for the parties, since there has been an acceptance by the user.

THE STATE ON THE WEB

2

Having defined the concept of social networks and analysed the general clauses established by their contracts of adhesion, we have now a general outline of the functions played by these virtual platforms. On that principle, we will now analyse how public administrations, in any of their forms or levels, make use of them.

This phenomenon has not gone unnoticed for scholars and academicians who have devoted themselves to analyse it, trying to understand, on the one hand, the need of the States to be part of these networks and, on the other, the social, political and economic impact their use brings about.

Many studies have been made in relation to the impact of the use of social networks by public administrations. Among them, we could mention Calderón, 2008; Criado and Rojas, 2012; Valenti and others, 2015; Criado and others 2015. Broadly speaking, these works point at the impact the use of social networks has had in the performance and development of management in public administrations, putting special emphasis on the way in which the managerial operations of the States who want to show signs of transparency, efficiency and efficacy have changed.

All of them agree that the emergence of virtual platforms has brought inestimable benefits to the sphere of the State. Furthermore, they share the idea that public administrations have the compelling need of having a presence on the Web through the virtual platforms.

Their use is key in the government's agenda: from an administrative and democratic point of view, they become essential not only for the citizens but also for the administration itself.

By having a presence in the social networks, the State conveys an image of transparency, trustworthiness, efficacy and management achievements, which is shown openly, in a direct manner and with a social perspective. That presence sheds light on the policies that the government and the State put into practice, which has a very positive impact on a social and political level and adds to the development of a sustainable Estate.

Far from the obscurantist view of public management, which was detrimental to the State both inwards and outwards, publicity on digital networks has drawn citizens closer and generated respect and trust in terms of institutionality, a concept with negative connotations before their use.

Virtual platforms have a vast spectrum of possibilities: they can be used to publish judicial rulings, public works presentations and services available for the citizens, and they may also become a powerful communication tool which may determine an electoral victory.

The 2008 United States election is a clear example of this: Barack Obama presidential campaign took place almost exclusively on the social networks. This allowed him to reach the White House with the largest share of voters, who had been previously engaged in the virtual platforms with the highest number of users (Carr, 2008).

To illustrate this point, we could mention some countries whose States are active users of social networks, something which has become quite significant to them. That is the case of the United States; the White House official Twitter account twitter.com/WhiteHouse, has 17 million followers. Spain, for its part, is registered under the official account of the Spanish Government twitter.com/desdelamoncloa, which currently has more than 0.5 million followers. In the same way, the State of Colombia is registered as a user since 2011 under the official account <https://twitter.com/infopresidencia>, which has more than 700,000 followers.

All the above-mentioned countries have an official presidential account, and also official accounts for each of the several agencies that make up their Public Administrations. Those accounts make an important communication and management work to have presence in the social media, clearly aiming to be part of a reality they have to involved in.

The number of followers or friends of each of those accounts is quite significant and they are continuously growing. That fact shows the importance of these platforms and how relevant it is for the States of different countries to increase their presence and posting frequency on them.

Presence in the social networks is nowadays so interesting that even the Judiciary has been involved in certain affairs related to accounts considered to be public. That was the case of the American Federal Justice when it recently ruled that the President of the United States had violated the First Amendment of the American Constitution.

Donald Trump had blocked a user from his Twitter account. The Court considered that when it comes to the President, his account is a public forum whose restriction would constitute discrimination that violates the applicable legislation (Kludt, 2018). President Donald Trump Twitter account (@realDonaldTrump) has currently more than 56 million followers.

Through its different agencies in all levels of the administration, the Argentinian State has also become a permanent and very present user of virtual platforms such as Facebook, Twitter, Instagram, and even Snapchat.

The new forms of communication have outdated the old access methods to public information, justice and any other management action performed by the State agencies, since the number of government entities has increased.

The Argentinian Government spends an important amount of the National Budget in the management and control of the social networks. In that sense, it created the Citizen's Bond Committee, dependent on the Presidential Secretariat of Public Communication.

The entity has 100 employees whose role is to design communication strategies in the social networks.

In 2016, the Government assigned to that Committee more than 160 million Argentinian pesos from the National Budget. The argument employed is the need of communicating acts of government and the direct bond that the use of virtual media establishes with the citizens. (Recalt, 2016)

This gave rise to multiple controversies (Alfie, 2016). In spite of them, it is possible to say that, according to Section 11, subsection 2), paragraph c) of the Personal Data Protection Act No. 25.326, and pursuant to its powers, the State is entitled to share with its own agencies all data derived from State Entities.

In Facebook, the official account of the Presidency of the Republic of Argentina is <https://www.facebook.com/casarosadaargentina/>, and it has more than 1.6 million users. In Twitter, the official account is <https://twitter.com/CasaRosada>, and, as the Facebook account, it has numerous followers.

Effectively, the examples mentioned allow us to see the presence of the State in the social networks. We have taken those two accounts in a descriptive way, since there are multiple accounts from State Agencies dependent on the National, Provincial and Municipal branches.

In effect, the Argentinian State is a user of social networks. To be one of them, it had to accept the contracts of adhesion analysed in the previous section. By accepting them, the adherent, in this case, the State, creates a legal bond that brings about unfavorable legal consequences for the State and has an impact on third parties, or more precisely, on the people governed by it.

In that sense, it is also possible to debate whether the State should abide by the Consumer Protection Law No. 24.240, whether it should be treated as a regular consumer, or whether a new legal figure contemplating the special nature of this user should be created. Nevertheless, the topic is beyond the aim of this work. We will only say that currently, according to the applicable law and since we are in the presence of a legal void, the State should be considered as a user or a consumer as described in the above-mentioned law¹.

It is not possible to find specific legislation that can be applied to the use of social networks by the State. Therefore, it will be necessary to explore all the legal corpus to establish which laws may be applied in that case.

Generally speaking, when comparing the legislation of several countries, it is only possible to find general guidelines on the use of social networks by the State. At first sight, it is not possible to find laws which establish terms and conditions with the companies owning virtual platforms that acknowledge a priori that the user accepting the contract is not an individual but the State, through its agencies. Such user requires concrete and specific laws which allow it to make an adequate use of the networks, complying at the same time with its applicable legislation.

Among other cases, we could mention Mexico, which has a Handbook of Policies and General Guidelines on the use of Virtual Social Networks by the Government of the State of Mexico (Gobierno del Estado de México, 2010), which establishes clear policies as to the general guidelines to be followed by the State when using social media. This handbook was designed to set goals to make the most of all the benefits provided by the social networks.

Countries such as Dominican Republic also have general guidelines related to the use of social networks by the Public Administration, which are laid down in the Policies of Social Networks Accounts of the Government. They establish certain strategies to be taken into account in the use of virtual platforms, and certain policies for them to be used correctly.

With regard to Argentina, the country does not currently have a legislation which particularly rules the issues being analysed. Even so, there have been important and paradigmatic changes lately in relation to communication strategies. In fact, several entities to modernize the Public Administration have been created, which shows a clear intention of the Government of having a strong virtual presence in the social media.

In the legal aspect, it is only possible to find that according to Resolution No. 13345/2017 of the National Directorate of Digital Content, there has been established a control regime which is only applicable to the opening and registration of social networks accounts by State agencies. The accounts owned by officials and employees of the National Government are not included.

Therefore, all the legislation ruling the matter is not sufficient to rectify the fundamental issue: that the State is accepting a contract of adhesion with different companies which collect personal data, whether or not the service is free, and that it ends being subject to certain clauses as if it were an ordinary individual, without considering its institutional peculiarities and the laws governing the public administration.

ON PERSONAL DATA PROTECTION

When referring to personal data, it is impossible not to mention the description and special considerations included on Section 2 of the Argentine Data Protection Act No. 25.326, which defines them as “information of any kind referred to certain or ascertainable physical persons or legal entities.” This

Act also references to sensitive data, making a difference from the above by considering them “personal data revealing racial and ethnic origin, political opinions, religious, philosophical or moral beliefs, labor union membership, and information concerning health conditions or sexual habits or behavior.”

For the purposes of this article, this difference is not substantial, since when talking about personal sensitive data we should always take into consideration the special and particular features of each case.

The issue of personal data protection appears as one of the fundamental factors when it comes to using social networks. As analysed in the terms of service, by accepting a contract of adhesion to the platform, the user gives consent to have his/her data transferred to and processed in the United States. Pursuant to Section 16 of the Facebook Statement: “Special Provisions Applicable to Users Outside the United States. We strive to create a global community with consistent standards for everyone, but we also strive to respect local laws. The following provisions apply to users and non-users who interact with Facebook outside the United States: 1.-You consent to having your personal data transferred to and processed in the United States...”

In Argentina, the Personal Data Protection Act No. 25.326 defines on Article 2 that personal data are: “Information of any kind referring to defined or definable individuals or corporations.”.

This law stipulates the minimum guidelines as to the quality of the data received. Those data must be true, adequate and pertinent, and they could only be used for the purpose or object they have been collected for. Their processing is only allowed after the free, expressed and informed consent of their owner.

In the same way, in relation to data assignment and international transference, Articles 11 and 12 of the above-mentioned law establish, respectively:

“Art. 11.- (assignment). Personal data subject to processing may only be assigned to comply with purposes directly related to the lawful interest of both assignor and assignee, with prior consent of the data owner...”

“Art. 12.- (international transfer). 1. Transfer of personal data of any kind to any country or international or supranational organization is hereby forbidden if adequate protection is not provided”.

Indeed, we find ourselves in a situation in which the State, who should guarantee the enforcement of the laws which comprise the Argentinian legislation, not only does not guarantee the enforcement of the laws, but also deliberately violates them.

It is clear that this occurs because of the eagerness to use new communication mediums, have direct contact with the citizens without the mediation of the press and implement new ways of Public Management.

The State, as the most powerful organization in society, continually collects data from the citizens related to every aspect of their lives. Within the mass of data that constitute its base, it is possible to find information ranging from personal information to racial or ethnic origins, passing through issues referred to health, political affiliation or personal assets.

This is a very sensitive aspect and it requires a deeper study. The State, in all its branches and levels, is the most important data collector. The amount of information it collects from the citizens is incalculable. It stores a person’s date of birth, level of education, localization, medical history and even his/her criminal record.

In this context, by using the social networks and posting content on them, which always relates to the citizens, the State is not only making use of the important benefits provided by the platforms, but it is also assigning all those data to a foreign company allowing it to use them in an indiscriminate way, without any kind of restrictions or accountability.

The excessive violation of the data protection laws by the State has many steps. The first step is the collection of data, the fact of not informing the owner about the processing or destination of those data, and the absence of the tacit and expressed consent required by the legislation. Then, there comes the transfer of data to a foreign company to have them processed in a foreign country, without the owner's expressed consent. Finally, the owner ignores the treatment the collected data will receive and who has access to them.

To the situation described, an aggravating factor should be added related to the entities to which the State accepts to transfer all its citizens' data. They are companies which develop their economic activities and get astronomical amounts of revenues due precisely to the traffic, processing and reception of the data continually assigned to them by the users.

Since there is no distinction between the individuals and the entities providing information when the contract is signed, the Argentinian State, as well as all the States signing up to these social networks, submit themselves to the rules of another State, without having the possibility of exerting influence over their making or enforcement.

Nowadays, the transaction of personal data has increased exponentially. So much so that it is considered to be one of the most important businesses of the last decades. Taking this situation into account, and given the compelling need of giving more protection to personal data, the European Union enacted the General Data Protection Regulation (GDPR). This Regulation increases data protection and establishes clear stipulations as to their processing and transference. It is expected that the legislation of the rest of the countries will also increase data protection and establish severe sanctions in case of infringement.

Argentina has been one of the first countries in the region to include in its legislation the issue of data protection, understanding their importance and the need to protect them. Currently, the process begun by those guidelines is being reinforced. For that reason, the country has proposed certain legal amendments which tend to strengthen data protection in accordance with the GDPR.

In that sense, certain countries of the region, such as Chile and Brazil, have proposed significant changes in their personal data protection laws. In line with the European legislation, the Latin American countries have considered that increasing data protection is quite relevant within the current context of massive access to computers.

Nevertheless, the progressive legislation which guarantees the protection of data is not consistent with the daily processing of data in the social networks accounts of the public agencies. There, it is possible to find posts showing pictures of minors, addicted and vulnerable people, and convicts, along with their personal data to have them identified more easily. As said before, all those data are freely transferred and assigned to the social network in which those pictures are shared.

Therefore, it would be important for the controlling bodies to exert the necessary control mechanisms to allow the Argentine State to enforce the applicable laws that have been promoted and enacted by itself.

This analysis focuses on the violation of the protective data protection laws by the State in spite of its own nature within the realm of the rule of law and its inherent obligation to protect every aspect of the lives of the citizens it governs, including their personal data. The analysis would be very different if we were dealing with a private company or the media themselves, since neither of them has the same obligations of the State.

ACCESS TO PUBLIC INFORMATION AND THE DUTY TO COMMUNICATE

The American Convention on Human Rights, or Pact of San José, Costa Rica, was approved and enacted by the Argentinian Congress by Law No. 23.054 on September 5th, 1984. With the Constitutional Reform of 1994, it was incorporated to the Magna Carta and enjoys constitutional status through Article 75, Subsection 22.

Its articles protect the citizens' right to privacy, and the rights of freedom of expression, conscience, reply, association and religion.

In its article 11. 2, it stipulates that: "No one may be the object of arbitrary or abusive interference with his private life, his family, his home, or his correspondence, or of unlawful attacks on his honor or reputation".

In this sense, the fact that the Argentinian State accepts a contract without being able to negotiate the clauses with the companies imposing it, which submit its regulation to the laws of another State, poses a risk in the compliance of the constitutional legislation.

The State is obliged to provide the necessary information for the citizens to exercise their rights. But the choice of doing so through virtual platforms developed by oligopolies, which set regulations to solve any claim or dispute in a foreign territory with laws of its own, may put the guarantees of the citizens against the wall to favor multimillion-dollar businesses and geopolitical interests that do not represent them.

The consultations, comments and horizontal interactions that take place when posting on the state agencies accounts allow to keep a record of citizens with specific characteristics.

In the cases analysed for this work, we have found pictures, videos and testimonies of citizens regarding the services provided by each of the state agencies.

In this way, elderly people declare the amounts and taxes that they pay for loans asked to the Social Security system, minors are exposed in photographs taken in schools dependent on the Ministry of Education, and residents of the City of Buenos Aires appear in pictures illustrating public works, services and activities performed by the autonomous government of the City.

On the other hand, although most of those people are users of these platforms, and therefore their personal consent exempt the companies from responsibility, there have been cases of arbitrary censorship: they are the result of the application of rules derived from non-universal cultural guidelines, and constitute examples of intervention over the cultures, practices and habits of other people.

This arbitrariness affects many citizens who use the social networks and, in the worst scenario, the assignment of data allows the companies to have access to sensitive information related to ideological stances, religious beliefs, health condition, and any other aspect compromising the privacy of the citizens.

It can also be seen that when people make claims through the Web in relation to identity records or small-scale data thefts, upload transaction forms or have access to public proceedings, the traces of that information might also be collected to be processed in ways which are not specified in the contract proposed by the companies managing the platforms.

Then, in the trajectory of the user from the agency account to its web site, more information is assigned which might be used in an arbitrary way. The risk of inequity and failures in data processing have already had negative results, such as arbitrary detentions derived from facial recognition, or purchasing of information by certain corporations aiming to obtain ideological stances or health condition of certain people, all of which emerging from posts made on the social networks.

CONCLUSION

We are faced with a reality in which presence in the virtual media -not only for individuals but also for the States- is essential. Nevertheless, the acceptance of a contract of adhesion established unilaterally creates an undeniable asymmetry of rights and obligations.

There is an increasing number of States around the world which use the social networks as communication mediums, because they have understood that there has been a change in the forms of communication, and that using virtual platforms gives them a sense of transparency, efficacy and effectiveness. That use also allows them to avoid the mediation of the press and guarantees direct access to the segments aimed at without the intervention of third parties.

In this context, the existing legislation in many countries, including Argentina, is limited to lay down mere guidelines on the use of social networks, without addressing the main issue: the adhesion to a contract pre-designed by a company, which creates a legal bond with the State which has unfavorable legal consequences for it.

In Argentina, the State -by adhering to the social networks- systematically violates the Personal Data Protection Act. The paradox is that, according to the legal framework regulating its actions, the State should be the one to enforce the law and create the necessary mechanisms to duly protect the personal data of the citizens over which it governs, which should be protected under the principles of the international treaty that protects human rights and enjoys constitutional status.

In this scenario, the State does not have clear processes, public policies and regulations on the use of social networks, not only regarding their administrative use, but also as to the conditions of use and processing of data it should be subject to.

The control mechanisms established by the State should be firstly aimed at adjusting the legal system to the current reality. Furthermore, it is most relevant that the State, under its legal authority, builds the necessary negotiation processes with the companies owning virtual platforms, to design bilateral contracts with clauses and stipulations applicable to the State as such.

The State has the obligation of activating its own control mechanisms through the appropriate entities in order to exercise control over data protection, violation of intellectual property rights, access to information and, basically, the right to privacy.

This should be done not only to protect itself, but also to justify its own purpose of existence: to protect, guarantee and safeguard the protection of the rights of each and every citizen.

Jawaharlal Nehru University, India

INTRODUCTION

The cyberspace emergence has created a new reality with transnational connection providing a venue for growth and also for contestation (Chourci, 2012). Defining the characteristics of the cyberspace includes various attributes such as; diffusion of power, ease of accessibility, low cost of entry, attribution, i.e., anonymity (Nye, 2011). The cyber domain position is characterized as a “transnational domain for information and economic exchange, which contemplates the transnational nature of the internet and the problem of global governance” (Kiggins, 2014). Definition of cybersecurity has constantly shifted to reveal the growing number of threats and new areas affected by the attacks. The case of UNGA resolution 53/70 where the modification of definition from the phrase ‘may adversely affect the security of the state’ in 1999 to ‘may adversely affect States in both civil and military fields’ in 2002 reflects the change in definition due to evolving nature and increased threats (Radu, 2014). Effectively, cybercrime was seen majorly as a technical issue, however, the course changed with the increase in incidents and the need for regulating it. The effective cost of cybercrime has increased with sophisticated tools being employed for a criminal purpose especially with the rise of ransomware as an industry. The concern arises from the fact that the average cost for the enterprises was \$11.7 million of cybersecurity due to cybercrime, with an increase of 27.4 percent each year (Accenture, 2017). Platforms like Convention on Cybercrime in 2001, World Information Society in 2003, have pushed for a ‘global culture of cybersecurity’ and laid the foundation for the effective policymaking at the international, regional, and national level. Moreover, the international scenario is constantly molded by the sophisticated cyberattacks, global geopolitical shifts, and social media empowered by political move with the divergent position of the states. The variance is visible in the cyber legislation with varying definitions, development with one paternalistic group of countries advocating state sovereignty while other members promoting freedom of internet and role of private companies

In this perspective, the article aims at presenting and analyzing the state of the growing threat of cybercrime and the resultant laws being enacted at the international, regional and national level by the countries to counter it. The first section includes the background, including an overview of cybercrime being defined in the various literature. The second section includes various efforts presented on cybercrime legislation including the multilateral instruments such as the convention on cybercrime by Council of Europe, United Nations resolution apart from regional and national efforts. The third section analyzes the challenges of jurisdiction, sovereignty, and privacy and the various responses in the form of legislation being laid out. The fourth section proposes a model for the effective cooperation in the form of balanced multi-stakeholder in light of growing internationalization of the cybercrime.

DOI: 10.4018/978-1-5225-9715-5.ch025

BACKGROUND

2

Literature Review

The research on the cybercrime has focused on analyzing it from various perspective, including the technological, sociological, criminology, psychology, and economic perspective. David Wall (2001, 2007) in one of the early analysis puts cybercrime on the basis of behavior lists (i) Cybertrespass/ hacking (ii) Cyberpiracy (theft of intellectual property) (iii) Cyberpornography (iv) Cyber violence (harassment/ hate speech) as the problem exists on the nature and extent. Later an addition was made to the computer-assisted crime by Susan Brenner (2010) as a social practice with the addition of the cyberspace to all aspects of crime. Due to this addition; cybercrimes are defined on the basis of the “computer enabled” and “computer facilitated” activities. It is similar to the difference earlier categorized by Brenner (2007) of traditional crimes and more specifically defined cyber offenses. The UK investigation agencies make the distinction between the *cyber-dependent crimes* committed through computers directed against computers and other as *cyber-enabled crimes* (Wall 2007). Similarly, (McGuire, 2012) described the cybercriminal groups in the form of “swarms and aggregators” with three types, ranging from the almost virtual conducting illicit activities, hybrid criminal groups and as facilitators mainly traditional organization criminal groups involving in trafficking, gambling, etc.

The definition includes the cybercrime as a form of social practice, which was further articulated by Yar (2013) considers the debates cybercrime not as a single crime but as a broad range of illegal and illicit activities that have effects on societal, political, economic effect. Emilio Viano (2015) in evaluating cybercrime from a societal perspective, considers it as a vastly unregulated field presenting the challenge among policymakers for effective cybercrime regulation. Holt and Bossler et al. (2016) make the distinction that the early computer crime till the 1990s was referred to computer misuse and later with the development of computer and internet, the focus is on offenses in an online environment. What is constructed as an association of crime with cyber is related to the usage of this emerging domain for the traditional criminal activities plus some emerging from the cyber domain. The term “cybercrime” is used to describe a range of offenses, including traditional computer crimes, as well as network crimes (ITU, 2014). Gabriel Weimann (2015) considers the association of terrorism with the cybercrime, where the terrorist has exploited the internet for various means ranging from propagating radical messages to financial gains. Many authors have attempted to look at the extent of the harm caused by the cybercrime empirically which have varied across the reports and limited the real extent in the policy-making (Klahr 2017; Markus Rieke, Rainer Bohme 2018). From a psychological perspective (Kirwan, 2018) in quantifying cybercrimes and propose the effective policing, deterrence means and introduction of a capable guardian to deter the criminal activities. Susan Brenner (2012) identifies the association of the migration of the traditional crime into the cyberspace along with new distinct cybercrime and the need for developing new law for it. Several national laws globally are outdated and face the unique challenge to prosecute them.

Cybercrime Development and Law

The cybercrime originated early on with the spread of networked computers and the legislation for the prevention of it. One of the first legislation was enacted in the US was the *Access device fraud Act* of 1984 for stopping counterfeiting using electronic devices, including computers. The first major cybercrime incident originated in form of Morris Worm which affected computer system in 1988 in the US was

prosecuted under the *Computer Fraud and Abuse Act* passed in 1986 which led to the criminalization of the acts of illegal use of computer. Later sophistication of criminal activities in the cyber domain led to the *Economic Espionage Act* of 1996, making the stealing of the trade secrets and criminal act. New avenues for exploitation because of evolving technology, has brought criminal usage of the computer. The most important change in the cybercrime has been the transition from the early curiosity-driven hackers to financially motivated groups, organized and systematic in the manner (Smith, 2015).

The sophistication of the development of cyberspace has led to challenges for the legislation to deal with the new emerging exploits used by the offenders. The legal approach takes into consideration the efforts for criminalization, (ii) measures for investigation and evidence (iii) harmonization of laws (iv) institutional cooperation, and (v) incident reporting (Appazov, 2014). In defining nature (Brenner, 2010) states the factor affecting cybercrime are proximity, attribution, and lack of physical evidence. Due to the lack of universal definition, the international and regional instrument has been on defining cybercrime on the basis of “set of conduct, making it an umbrella term” (Hakmeh, 2018). Cybercrime is “unbounded crime”; the victim and perpetrator can be in different cities, different states, or different countries. Thereby concealing the identity and making evidence gathering and prosecution difficult.

The recognized base for cybercrime as established in the international documents including Convention on Cybercrime, Tallinn Manual, ITU are:

1. Availability (of the data without any hindrance);
2. Integrity (Authenticity and non-repudiation);
3. Confidentiality (Information for the concerned user only)
4. Computer-related offenses
5. Content-related offenses (includes data theft, password)
6. Copyright –related offenses

The cybercrime legislation refers to policies, laws, recommendations enacted for the prevention and mitigation of computer-related crime. Cybercrime includes traditional forms of crime such as fraud, identity theft, and stalking, bullying, and new emerging forms such as botnets, zero-day exploits, phishing. Cybercrime legislation plays an important role, at both national and international level; in preventing and combating cybercrime. The case for the “formal collaboration” has developed over the years in cyberspace with state-nonstate actors; active state encouragement; state incapacity to control private illegality (Boardhurst, Grabosky, Alazab, & Chon, 2014). ‘Cyberization,’ i.e., in the events such as the 2007 Estonia cyberattacks which rendered critical services ineffective like banking, communications, and government websites reflects the growing offense. The act was being considered under as the potential of having an armed attack. In response, the legislative position of the states has changed over time with the inclusion of the offensive cyberattacks which includes the creation of the cyber military command such as the US Cybercommand and similar efforts by other countries. NATO in 2014 extended the cyber defense in the same category as kinetic attacks. On similar lines, the UN concluded that article 51 referring to the self-defense applied to the cyberspace.

Large scale espionage activities sponsored by the state, such as the large scale Chinese espionage unit revealed by the (Mandiant Report, 2013) reflects a growing association of state and sponsored hackers. The NSA leaks by Edward Snowden exposed a global surveillance program being conducted for the collection of confidential information, including private email and telephone communications (Buchan & Tsagourias, 2016). The consideration of the cyber-related infrastructure as vital in the form of national security have formed an ambit of offensive operations along with the established defensive measures

enacted. The political and economic considerations of cyberspace have changed the definitional aspect of what is accepted and what is not. In the International Strategy for Cyberspace (2011), the United States held for the offense cyber operations defending critical infrastructure at a time when it was facing state-led data breach attacks and economic espionage incidents.

The development of adequate legislation and within this approach, the development of a cybercrime related legal framework is an essential part of a cybersecurity strategy (Brenner, 2010). The integrity of the ICT of a state is essential for the security and economic wellbeing and therefore established national cybersecurity strategies need to reflect it. The steps for the cybercrime legislation includes the criminalization of the acts affecting the integrity, confidently of the computer systems. The early efforts include the OECD in 1983 and the Council of Europe on the criminalization of the offenses in 1989 [recommendation]. Various studies conducted for the crime committed led to studies in 1995 and 1997, which eventually culminated in the Convention on the Cybercrime. The next section discussed the important policies on cybercrime, which includes binding legislation like Convention on Cybercrime and voluntary agreements by the United Nations.

MULTISTAKEHOLDER INSTRUMENTS ON CYBERCRIME

International Approach to Cybercrime

The international efforts for cybercrime consist of international law, development of norms such as the UN GGE (United Nations Group of Governmental Experts), Budapest Convention on Cybercrime, facilitating bilateral agreement and developing deterrence policies in the wake of the development of the attack capabilities. The international agreement consists of the formal and the informal structure and; are voluntary in nature. The broad range of institutions has developed for the construction of facilitating and promoting responsible behavior in cyberspace. This organization operates from the global level to the regional level, ensuring standard operations on the internet and ensuring its security.

The Council of Europe (CoE) Convention on Cybercrime

The convention is the most comprehensive legislation on cybercrime “common criminal policy,” aimed at the protection of the society” at the international level. It was opened for signatories in 2001 at Budapest and remained the only binding instrument in the area of cybercrime (Council of Europe, 2001). The European Committee on Crime Problems established a group in 1996 to form a committee of experts to tackle the issue of cybercrime. The principal rationale for this move was the growing number of cyber-offenses and the need for the updating of the criminal law.¹ Apart from the members of the CoE, there were states including the United States, Australia, South Africa, and Canada in the negotiations process. Through several rounds of meeting and drafts, the Budapest Convention on Cybercrime was opened for signature in November 2001 at Budapest, Hungary to both the members and the nonmembers. The convention entered into force in 2004.

The convention is divided into four chapters covering the criminal acts, laws, enforcement mechanism. The second chapter covers the domestic level procedures for the “criminalization of substantive offenses” (chapter 2-10). An important aspect introduced in the convention related to criminal prosecution was the “collection of evidence in electronic form of a criminal offense.” The significant portions

Institute of Electrical and Electronic Engineers	Interpol	

Source: Key Entities and Efforts with Significant Influence on International Cyberspace Security and Governance [(US GAO, 2010), (Chourci, 2012)]

which cover for the criminalization included: The interference with the data/ System or Illegal Access (ii) Misuse of Devices for crime commitment (iii) Computer-related Forgery and Fraud (iv) Offense related to child pornography. The third chapter laid the international instrument for cooperation, including the mutual legal assistance treaties, transfer of data, and the judicial. For the cross border investigation, the convention facilitates the Laws on the International Cooperation for the purpose of investigation and proceedings. It lays that “the Parties shall afford one another mutual assistance to the widest extent possible” for cooperation on criminal investigation. Also, Article 35 provides for the 24/7 network for the real-time assistance of data information.

In addition, the Council launched the Additional Protocol on Cybercrime on Racism and Xenophobic Nature in 2003 and asserted that the “criminalization of the racist and the xenophobic propaganda committed through the computer systems” and the need for adequate legal responses national and internationally.² The convention forms an integral part on the privacy concerns and the balance of freedom of expression. The council implementing committee T-CY has been regularly updating the convention and negotiation for 2nd Protocol on “enhanced cooperation on cybercrime and electronic evidence” is underway (Council of Europe, 2018). CoE project on Cybercrime includes the harmonization of laws, judicial training, public-private partnership such as the focus on Southeast Europe noted for cybercrime groups and their association with the dark web. The convention is limited to the private actor limiting the scope and does not include action against the states.

United Nations

United Nations (UN) has remained the principle international organization for the development of norms principle and policies in the field of information technology. The role of the UN is to drive the divergences and the harmonization of the laws to reach a common understanding of the laws which can be applicable globally and interoperable with the regional and national laws (Schjolberg & Helie, 2011). The policy-making on the cyber norms at the United Nations consists of two main streams- one politico-military focusing on the cyberwarfare and an economic stream focusing on the cybercrime (Maurer, 2011). The ITU divides the UN organizations ‘work on cyber-security as follows: (1) Combating cybercrime: ITU

and UNODC; (2) Building capacity: ITU, UNIDIR, and UNICRI; (3) Child Online Protection: ITU, UNICEF, UNICRI, UNODC forms the major effort in cybercrime (UN ITU 2010 report). Various bodies, committee's forms part of the policy-making and implementation, including primary bodies the General Assembly and Security Council.

The early legislation on the cybercrime was the UN resolution 55/63 on the *Prevention of Crime* in 1990, which related to the abuse of the computer. The 1998 resolution "Developments in the field of information and telecommunications in the context of security" introduced by Russia in UN General Assembly marked an important shift along with the exponential growth of the internet in the late 1990s (Maurer, 2011). Similarly, the UN resolution *Development in the field of information and telecommunications in the context of international security* (1999); placed emphasis on the development of the principles on international information security and help to combat information terrorism and criminality".³ UN resolution 55/63 and Resolution 56/121 are the main legislation on cybercrime laying framework for the criminalization of computer acts and laying the global legal framework for combating cybercrime (UN, 2001). The main proposition of the legislation is the (i) Eliminate "safe havens" for criminal misuse of information technologies (ii) Coordination of the law enforcement agencies (iii) Criminalization of the acts for violating confidentiality, integrity and the availability of the data. Moreover, the UN Convention on Transnational organized crime (2003) laid a framework for computer usage for criminal activities and the development of training, law enforcement.

A group of governmental experts was formed in 2004 with the aim of strengthening the security of the global information and telecommunication system. (UN, 2003). 2004 agenda was on the "Global culture of the cybersecurity," and the Tunis agenda in 2005 led to two important outcomes; the first was the creation of the Internet Governance Forum (IGF), and second, was the ITU for "Building the Action line C5 for the cybercrime". This action line eventually emerged in the form of the 2007 Global Cybercrime Agenda as a form of the norm-setting agenda on cybercrime under the working of the ITU based on five pillars including Legal Measures; Technical & Procedural Measures; Organization structure; Capacity Building; International Cooperation. The importance of the ITU in UN cybersecurity role is that apart from the organizational role, the agency also acts as an "autonomous norm entrepreneur." The practical guide to *Combatting Cybercrime: Tools and Capacity Building for Emerging Economies* focuses on capacity building of various stakeholders, including education, legal remedies (ITU, 2014). The UN-GGE in recent years has culminated into important consensus on the issue of applicability of international law on cyberspace in 2013 and conduct of state in cyberspace in 2015. Despite the failure to reach consensus in 2017 over the applicability of humanitarian law as the way forward for institutionalizing cyber norms. (Cherneko, Demidov, & Lukyanov, 2018)

REGIONAL LEGISLATION

Apart from the international organization, regional groupings have developed legislation regarding cybercrime in following the harmonization and taking into account the region considerations. The regional legislation has gained prominence as it entails steps for a stronger and detailed legal framework and periodic update of provision with the inclusion of new threat (Dominioni, 2018). This approach is essential as the differences in the region creates a need for a different strategy.

European Union

EU agenda recognizes the cyberspace as a critical area, and the legislation consists of the “larger scope of the EU policies recognizing the international dimension” along with the domestic (Renard, 2018). These are reflected in the “strategic partnerships” as part of the EU cyber diplomacy approach towards a common legal approach; put up in the 2015 cybersecurity strategy. European Union framework on the security of the Information systems, 2005/222/JHA2, and the protection of society (2006) are key directives for the legislation formed. It includes the “stronger national laws” and “severe criminal penalties” (European Union, 2005). The directive changed the institutional response with placing “emphasis rather on approximation” regarding criminal law improving cooperation among authorities and judiciary. (Foggeti, 2009) The directive was replaced by 2013 with the inclusion of new sophisticated attacks as “outlawing of Botnets and ‘using the same point contact as Council of Europe and G8’ for quick action response. (EU 2013)

With the number of cyber threats growing in 2011, the operational measures to combat cybercrime were strengthened. It led to the establishment of EU High Tech crime unit task forces, Cybercrime unit in 2013 with Computer emergency response units and EISAS. The Directive on Security of Network and Information System (NIS Directive) provided a regional wide common legislation on cybersecurity including measures including the illegal interception in the wake of the Snowden revelation apart from illegal data, system interference (Munroe 2017). It includes the formation of National CIST, data sharing collaboration, and harmonization of laws.

EU internal strategy was adopted in 2010 with the future layout for directives containing protection of the data and fundamental rights in the directive enacted. The European Union General Data Protection Regulation (GDPR) enforced in 2018 has changed the ways of privacy and security with “data as a fundamental right” at the individual level. This affects the way data is collected, processed and stored, where ‘consent’ is required for any form of data collected and to be reported to a competent national supervisory authority in case of violation (European Union, 2016). For cybercrime, the data handled is segregated by the authorities and the liability of the companies handling the data with fines up to 4% of the global turnover. These are important steps at times when data breach and the ransomware incidents have sharply grown. The legislation debate has a worldwide effect on the concern for privacy being placed along with security measures at the national level.

Other regional organization proceeds on the basis of voluntary agreement, Shanghai Cooperation Organization⁴ Agreement on Cooperation in the Field of International Information Security (2009) defines the “key concepts and main threats” to the information security. The agreement differs from other western conventions referring to the protection of the information security, including the socio-political, economic, cultural, and moral environment of the state” (SCO, 2009). The SCO legislation was adopted at UN ‘Code of Conduct for Information Security’ in 2015 which contains measures for the protection of information security [defined in a broad manner] with focus on the national sovereignty and data localization efforts to combat cybercrime.

The League of Arab States Convention on *Combating Information Technology Offences* (2010) the convention has drawn from the Budapest Convention in the provisions. (Hakmeh, 2018). However, the religious factors are included, which is unique such as “ideas and principle of terrorist groups.” The focus has been on the criminalization of acts and limitation of freedom of expression with vaguely wordings. (Hakmeh, 2018)

ASEAN, the organization of Southeast Asian states declaration to prevent and combat cybercrime was adopted in 2007, emphasize the “importance of harmonization of laws related to cybercrime and electronic evidence.” ASEAN Cyber Capacity Development (2016-2020) is part of the ongoing process to develop comprehensive region-wide legislation, enforcement with a comprehensive review of national laws and developing capacities (AT Kearney, 2018). The efforts become important as cybercrime are transnational in nature with the region witnessing massive IT growth.

African Union Convention on Cybersecurity and Personal Data Protection (2014) recognizes cybercrime as a “real threat to the information society in African Union” defined broad guideline to combat cybercrime and protection of personal data (African Union, 2014). It calls for the formation for national cyber strategy by each member state to combat cybercrime (Article 24) and the formation of National Data Protection authorities (Article 11). Similarly, other nonbinding efforts by regional organizations include the Association of Pacific Economic Community (APEC) which has security and prosperity steering group overseeing the efforts for the prevention of cybercrime. Similarly, the Organization of American States (OAS) has a dedicated Inter-American Cooperation Portal on the resources and data relating to cybercrime.

NATIONAL CYBERCRIME LEGISLATION

Various states have adopted the measures for the protection in the form of legislation enacted paving the way for the criminalization of the acts. The current position is that cybercrime legislation is as of now enacted by 135 countries out of which 95 are developing⁵, and still, more than 30 countries have not enacted any cybercrime legislation (UNCTAD 2018). The developed states still lead for international harmonization of the cyber laws, and several states follow the Convention on Cybercrime, which guides the member and the non-member states. National legislation contains measures to ensure the availability, integrity, and confidentiality of data and protection of the critical information systems. To keep pace with technology development, many countries use “generic language to generalizations” in cybercrime legislation reflected in the United Kingdom and US legislation.

In the U.S, the *Computer Abuse and Fraud Act 1987* are being used to criminalize the acts of illegal and illicit use of the computer along with the setting of computer emergency response network (CERT) (Viano, 2017). The issue of copyright infringement, intellectual property, and identity theft have been covered by various federal Act such as the 1998 *Identify Theft and Assumption Deterrence Act*. The increase of the ransomware as a significant cybercrime issue has led to the enactment *Economic Espionage Enhancement Act* of 2012 and safeguards for Intellectual property theft. In 2015, executive order 13964 was enacted by the Obama administration with the application of economic sanctions to hackers.

In the UK, the *Computer Misuse Act* of 1990 forms the base of criminalization of illegal access to the computer. However, significant addition has been added to such as computer misuse act in the UK in 2015, putting cybercrime to serious crime with increased imprisonment to 14 years. On the other hand, Australia government produced legislation titled the *Cybercrime Amendment Act of 2012* to implement all the clauses of the Convention on Cybercrime to strengthen cybercrime laws. The primary provision includes stronger communication measures “held by the carriers” required under warrant for investigation (Australian Government, 2012).

The Chinese cybercrime law introduced in the Penal Law of 1997 makes illegal access to the computer punishable and also includes the damage to the hardware of the computers. The 9th amendment to the Penal Law was placed in 2014 with penalizing network operators to failure of obligations and provide support, information to criminals. In the comparative paper by (Yong, 2011) between Chinese cybercrime laws and Convention on Cybercrime describes that the parties which have not signed the convention have used it as a reference point for legislation formulation.

Also, India, which is not a signatory to the Council of Europe, has modeled its cybercrime law on the United Nations resolution according to the harmonization of national legislation. Information Technology Act, 2000 forms the base for legal recognition to all electronic activities and making the criminalizing act of illegal access to a computer. Amendment to the law in 2008 have included liability of the companies for the data breach, e-commerce transactions, child exploitation online. The cybersecurity law of 2013 furthers the growing importance on infrastructure with specialized agencies and cooperation on the cybersecurity issues.

Apart from multilateral cooperation, bilateral cooperation between states serves as a *direct point of contact* resolving the disputes and enabling cooperation. Currently, the various bilateral agreement extends on several areas, including cybersecurity, data transfer, and law enforcement between countries. The U.S.- China agreement (2015) on the cyber-enabled economic espionage or the US-India cybersecurity agreement (2013) aims to strengthen security and cooperation. Similarly, Russia- China agreed on the ‘non-aggression’ garment with the aim to not attack each other ICT enabled systems.

SCOPE OF CYBERCRIME LEGISLATION: CHALLENGES

The cybercrime legislation has a considerable difference from the legislation on traditional crime with respect to the location of the criminal due to the issue of attribution. The physical presence is not necessary in the case of cyberattacks, as most of the crime is committed transnationally placing the difficulty of jurisdiction. As the legislation encompasses information security, the onus of securing privacy is difficult to reach. In the Convention on Cybercrime, article 32 (B) refers to the “transborder access to data where publicly available.” The interpretation has been dubbed as an overreach of the data leading states like Russia not signing the convention.

Jurisdiction

The applicability of the criminal laws in the international sphere takes place in the form of procedural law and substantive law. The principle of “Dual Criminality” places that the offender can be prosecuted irrespective of the place the crime was committed if the same set of laws exist in both the countries. Tallinn Manual 2.0 places the question of the extraterritoriality ‘from a new position. The “meant to be accessible” (rule 8 of the manual) is the determining factor that, if the counties access the public data from their territory [though located overseas] is not an act of extraterritoriality but the case of territoriality (Eichensehr, 2017). In adjudicating the case of the Microsoft v. the United States on the accession of the data located on a server in Ireland, Second Circuit court ruled in favor of Microsoft considering it overarching of the Stored Communication Act (SCA). However, the U.S Supreme Court overturned the

case as “unauthorized extraterritorial application” in favor of Microsoft. (*United v. Microsoft Corps.*, 2018). In the debate Cloud Act⁷ passed by the U.S Government amended the SCA and placed the capabilities to access overseas data [if it does not violate the law of the country] and access the data in the U.S [not targeting U.S citizens or person within the United States](Cloud Act 2018). Further, it allows the President to enter into an executive agreement for data transfers with other countries. The question of global enforcement found relevance in the massive ransomware attacks as Petya Malware, which was a series of Denial of Service attacks (DDoS) and affected computers in over 150 countries.

Sovereignty

The cyberspace has emerged as a new avenue for competition among various actors. State-sponsored cybercrime has increased over the years, where the states are allegedly committing cybercrime in the form of digital espionage, surveillance, and network interference activities. The problem of attribution, i.e., “who committed” has occurred with debates over digital evidence in prosecution. UN-GGE concluded that international law applies to cyberspace, state sovereignty, and the resulting laws; asserting the state rights in the domain. The actions are limited with the question of attribution and the prosecution of cybercriminals as in the case of Estonia cyberattacks in 2007 sponsored by Russia.

Rule 8 of the CoE holds the fact that a cyber-operation has been routed via the cyberinfrastructure located in a state is not sufficient evidence for attributing the operation to that State. The Group of 7 (G7) declaration on “Responsible States Behavior in Cyberspace” recognized on April 11, 2017 underlines that “the urgent necessity of increased international cooperation to promote security and stability in cyberspace consisting of the applicability of existing international law to State behavior in cyberspace, the promotion of voluntary, non-binding norms of responsible State behavior during peacetime” and reaffirmed “that the same rights that people have offline must also be protected online.”

Data Transfer and Privacy Concerns

Privacy has remained important and grown more central to the cybercrime legislation. The number of data breaches has escalated over the years. The need to identify and legislate to apply changes in this domain has become central to the recurring debates in the socio-political domains, triggered by daily cyber-related incidents. The legislation, in many ways, provides means to law enforcement agencies to store more data. At the same time, incidents of data breaching of identity theft, financial information has increased. The collection of the metadata under the Patriot Act and the Edward Snowden revelation has led to the increased concerns for the protection of data. Social networking websites such as Facebook has witnessed massive data breaches. The EU data retention directive of 2006 was annulled in 2014 by Ireland Court on the basis of fundamental rights to respect for private life and to the protection of personal data” (Digital Rights Ireland and Seitlinger, 2014). The set of factors are reflected in the emergence of the data localization by states including Russia, India, and China has emerged with the storage of user data within the territory and control of the major companies. EU privacy policy places the “adequacy protection” in personal data with the power to determine the country has “adequate level of data protection.”

RESPONSE

Legislative Position on Investigation and Enforcement

The case of global internet governance is as much a political as it is technical (Shull 2014). The European Council Guidelines for Internet Service Providers and Law Enforcement Cooperation, especially in the prevention, investigation, and data evidence cases⁸. The various mechanisms developed in the form of the formal and informal cooperation result as “requisite consensus,” which is still being developed (Munroe, 2017). Data forms the vital part of the information technology, and the effective legislation on the sharing of the data remains to be “complex and sensitive” with the information exchange diverse the trust deficit among the states (Rutkouski, Fostr, and Goodman, 2012). The actions driving the work of the international law enforcement bodies are in the position of advisory function. G7 cybercrime working group (Roma-Lyon Groups High Tech Crime Subgroup) developed 24/7 point of contact for “requesting on an emergency basis preserving electronic evidence and locate suspects” (OAS). It is especially important for the foreign government to request for electronic evidence to major ISP and extends to include 84 states⁹ as members.

Interpol, the major international investigation agency, consists of 190 states tends to aid the investigation agencies in various states. In the form of the capacity building initiatives, they prepare the law enforcement officials and monitoring of the “norms and instruments” connected to the cybercrime (Interpol, 2017). In 2010, the Global Complex for Innovation (GCI) was formed by its general assembly and later including the Digital Crime Center with the mandate of “global hub for cybercrime issues” (Schjolberg, *The History of Cybercrime: 1976-2014*, 2014) Partnering with the private players, remains vital in fight against the cybercrime. Interpol Global Complex for Innovation signed the data sharing agreement with British Telecom for “threat information exchange on data relating to criminal trends in cyberspace” (BT (British Telecom), 2017).

Global Multilateral Alliance¹⁰ as IMPACT formed in 2008 backed by the United Nations represents the partnering between the government and the private industry. The alliance has now 152 members with the services including emergency response service, identification of the cyber threats and sharing resources across the member states. The action is important for the states developing the national emergency response system for cyber threats (IMPACT, 2012). In the form of the institutional response, Europol the primary law enforcement agency in European Union, set up the European Cybercrime Center (EC3) to drive action through “cross- border investigation” and operations by partners with the private players.

There is a well-established informal process which supports the formal process (Smith, 2015). The other informal efforts apart from IMPACT include Meridian process which handles the regularly updated global reference book for Critical Information Infrastructure Protection policies and points of contacts for technical cyber emergencies in more than 50 countries. Besides this, the Global Cybersecurity Index launched in 2014 helps foster a global culture of cybersecurity and its integration at the core of ICTs (ITU, 2017). A financial Action Taskforce (FATF), an intergovernmental body formed by the European Council with the rationale of protecting the global financial system in 2014 published report on Virtual Currencies. The FATF group comprised of states including the United States and Russia laying out the key definition and developed a “risk matrix” for bringing clarity and understanding financial risk from cybercrime. The step is imperative as the ransomware industry has grown with the usage of new sophisticated tools such as Eternal Blue the tool used by NSA was leaked and used for Petya malware attacks.

At the national level concerns over the applicability of domestic law to international crime, situations sustain. In the case of the United States, the case of extraterritoriality applies with the provision of the Patriot Act and now Cloud Act allows for the “search and seizure of the data” publicly available. The measures and the issues in international law with the lengthy procedure involved the formalized channel for the collection of the electronic evidence is essential to bring cybercriminal indictment. This is especially important between states that are not a member of grouping like Convention on Cybercrime, e.g., China, India. The position is quite similar to the discussion by the UNGGE experts of the “publicly” available data in foreign territory.

For serving as the model legislation in cybersecurity, the EU e-evidence directive for improving the cross border investigation and the preservation of electronic evidence for criminal purposes, EU e Directive extends the service provider obligation with direct evidence production from one member state to other. The act is still under consideration with the criticism for the over compliance and the necessary safeguard for data. Also, way forward has emerged in policies of the European Union with the creation of a *single digital market* and EU wide cybersecurity strategy in the form of binding implementation. The Network and Information Directive (NIS) directive puts EU states to identify the strategic resources, common cooperation groups for sharing strategic information

The legislation for conducting the state behavior has also gained momentum with the UN GGE call for responsible state behavior, while private organization Microsoft called for a ‘Digital Geneva convention’ regulating state behavior in state-led attacks.

Cybercrime Regulation Proposed Approach- A Balanced Multistakeholder Model

Maurer (2011) contends that Internet governance has traditionally not been dominated by states but rather by the private sector and civil society. The increasing number of internet users have escalated the people affected by cyber legislation. This is the ——multilateral (states only) vs. ——multi-stakeholder (states plus private sector and civil society) debates, reflecting the position on the issue. Western countries have pushed for Convention on Cybercrime, while states such as Russia, China on alternate models of internet governance focuses on sovereignty. An important aspect is the reform of the internet governance stricter within which the domain name, registry, and the working of the internet lie. China, along with other developing states, demanded the reform of the ICANN, which distributes the domain name system on which the internet works. The current structure is dubbed as “legitimacy crisis,” especially the working of the structure as ICANN governing bodies. The events are more incited due to the activities of the events such as Edward Snowden leaks exposing large surveillance programs and the cyber legislation, the international consensus due to the working model of the internet governance where the western countries dominate the structure and legislation. The larger role of the ITU in the role in the building initiatives in the development of the national strategies, legislation, enforcement, and organization structures fulfill the digital divide. (ITU, 2012)

The proposed model views the process as balanced, equative, and collaborative of all the relevant partners, especially in the harmonization of legislation, sharing of data and effective law enforcement. Particularly, the model holds importance when the cybercrime in the developing countries has seen surge; with the states having “few or no laws against cybercrime.” (Kshetri, 2010)

Therefore, the capacity building initiatives in the development of national strategies, legislation, enforcement organizational structures is desperately needed (ITU, 2012). The formal structure is one way while collaboration is another, which includes the informal process, i.e., the inclusion of partners and mechanism along with government and its associated institutions. The UNODC report of 2013 emphasizes the primacy of capacity building for at all the levels of the individuals, governments, enforcement agencies. (UNODC, 2013). Human error in the cybercrime perspective constitutes 27 percent of the security lapses forming substantial loss (IBM, 2018). Therefore, the provisions for educating the users regarding the various protection mechanisms should be placed. The confidence building exercises are an effective way of further leveraging the relations. EU dialog with China in the form of 1.5 track Sino-European cyber dialog or U.S-China cybersecurity dialog reflects the developing effectiveness of cooperation on cybercrime issues. The Global Cybersecurity Index report 2017 concluded that “the collaboration of the developed countries in training of the local cybersecurity experts and more cooperation to assist them in cybersecurity development,” thus emphasizing the necessity for multi-stakeholder efforts. (GCI 2017)

CONCLUSION

The conversation of digital activities into crimes related to cyber technology has emerged as the base for the cybercrime policies at the international, regional, and national levels. Convention on Cybercrime is an effort towards harmonization of laws at the international level. Yet, it remains the only binding instrument at the international level, reflecting the urgency to resolve issues that need to be addressed. The growing prominence of organized crime and state-sponsored groups has furthered the need for global cybercrime regulation. The UN nonbinding voluntary basis mechanism has worked towards the institutionalizing and garnering consensus among states for developing and implementing cyber laws, though on a limited scale. EU GDPR presents the way forward, strengthening the data collection mechanism and entrusting privacy safeguards, especially in the wake of data exploitation by numerous actors for malicious purposes. The proposed balanced multistakeholder model can be an effective mechanism for bringing comprehensive international efforts to combat cybercrime. With an emphasis on developing countries, which include a vast amount of internet infrastructure and users, their role becomes prominent in the governance of the internet and policymaking.

KEY TERMS AND DEFINITIONS

Cloud Act: Cloud Act is the U.S. legislation related to the transfer of electronic data with provisions for obtaining data for evidence and prosecution and also regulating transfer for foreign governments.

Cybercrime: The usage of the computer and its related technologies for the purpose of disrupting, with the motivation to gain financial gains or causing political, social, and psychological harm.

Dark Web: The dark web is part of the web that is not accessible on general search and can be accessed through specific hosting servers. It consist of the information and tools that are illegal by criminal, terrorist.

Denial of Service Attack (DDoS): The activities which disrupt the services of the computer rendering the computer usage ineffective for the user.

Mutual Legal Assistance (MLAT): MLAT are formal investigation request made by the states for the access of the data located in other country for the purpose of investigation and extradition.

Phishing: Is defined as the method of cyberattack which are employed to capture the sensitive information including passwords, personal information for the malicious purpose through means such as deceptive emails.

Ransomware: Is defined as the illegal access to computer system using malware for the purpose of gaining control of the system with the motivation for financial gains.

Regulating the Internet

David T. A. Wesley

Northeastern University, USA

INTRODUCTION

The early history of the Internet was a time of naive optimism that the medium would create a new era of global free speech. In 1996, John Barlow, an Internet Pioneer and founder of the digital rights organization known as the Electronic Frontier Foundation (EFF), wrote “A Declaration of the Independence of Cyberspace” in which he declared that governments “have no sovereignty” over the Internet. Cyberspace was “naturally independent of the tyrannies” of nation states, he wrote, and any attempts to control it would ultimately fail (Barlow, 1996).

More than 20 years later, Google is creating a search engine for China that censors any content deemed disagreeable to the central government, Facebook is being used by hate groups to organize lynch mobs and commit genocide, and Internet-connected cameras are being deployed for mass surveillance. The Internet has also become a primary tool for state propaganda and “fake news” aimed at undermining democracy and free speech.

Despite these challenges, court decisions that protect computer code under the First Amendment of the United States constitution have helped create a free flow of knowledge and tools that can be used to counter such threats. Given the ubiquity of American technology companies, U.S. legal precedents and decisions can have global implications.

FOCUS OF THE ARTICLE

Established U.S. law has long held that computer code is a language, like any other language, and is therefore subject to same free speech protections afforded other forms of speech under the First Amendment of the United States Constitution. Computer code also protects free speech through cryptography that enables protected communication between two or more parties.

This article will consider the legal history of computer code as free speech and how it can be used to promote other forms of free speech through cryptography and secure communications. It will further argue that the deep web and dark web are direct results of these precedents and while they can be abused by cybercriminals and malicious state actors, they are also indispensable in promoting free speech and human rights.

BACKGROUND

The telegraph was one of the first uses of technology to communicate information. In the early 20th century, the language of automatic telegraph operators in many ways resembled computer code. For example, when a telegraph operator would send a message, the message was encoded with special

DOI: 10.4018/978-1-5225-9715-5.ch026

terms – dux for duplex, mux for multiplex, gm for good morning, etc. With the advent of the automatic telegraph, words such as printers, machines, and bugs took on new meaning. A bug, for example, was an electrical disturbance that could cause the signal to drop out momentarily or even cause the system to hang (Brackbill, 1929).

Similarly, the first computer engineers created unique computer codes that later developed into their own languages. In the 1950s, as computers became more complex, engineers began to recognize the problem of making this increasingly complex machine language intelligible. Brownson (1953) wrote, “In communicating with each other, we seek to communicate concepts; in defining terms for manipulation by computers, man will have to find out exactly what he believes and make coherent and integrated sense of it.”

Bar-Hillel (1953), a pioneer in machine translation, saw this as “a real challenge for structural linguists,” but he also believed that it would only be a matter of time before machines acquired a “semantic organ.” “One of the decisive steps in certain methods of machine translation is the determination of the syntactic structure of any given sentence in the source-language (i.e., the language from which we translate) to a required degree of explicitness.” As a result, computers that “were originally designed to solve certain mathematical problems... might well be recombined to yield similar results in noncomputational fields” (Bar-Hillel & Bar-Hillel, 1951).

Already, Brownson and Bar-Hillel were expressing two views that would later become central in the debate over computer code as free speech. Brownson saw computer code as a form of communicating what one believes, whereas Bar-Hillel saw it as a means to solve problems, including those that were strictly mathematical and those that would later develop in noncomputational fields. If computer code expresses ideas and beliefs, it could be a protected form of speech under the First Amendment to the United States Constitution, but if, as Bar-Hillel says, it is merely a method to solve problems, then it should not be protected.

Two of the earliest cases to consider the question of the First Amendment status of computer code involved export restrictions on cryptography programs. In 1996, President Clinton issued an executive order restricting the exportation of encryption products in the interests of national security. Henceforth, encryption technology would be “designated as defense articles in Category XIII of the United States Munitions List and regulated by the United States Department of State pursuant to the Arms Export Control Act” (Executive Order 13026, 61 Fed. Reg. 58767).

In *Karn v. United States Department of State* (1996), the court made “no ruling as to whether source codes... fall within the protection of the First Amendment,” but clearly suggested that it was not protected when it stated that “[s]ource codes are merely a means of commanding a computer to perform a function.” In this case, the court applied the O’Brien test (*United States v. O’Brien*, 1968), holding that the “government regulation at issue here is clearly content-neutral” and that the government had a compelling national security interest at stake.

This contrasts the position in *Bernstein v. United States Department of State* (1996), in which the Honorable Marilyn Patel held that “the particular language one chooses [does not] change the nature of language for First Amendment purposes. This court can find no meaningful difference between computer language, particularly high-level languages as defined above, and German or French. All participate in a complex system of understood meanings within specific communities. Even object code, which directly instructs the computer, operates as a ‘language.’ When the source code is converted into the object code ‘language,’ the object program still contains the text of the source program. The expression of ideas, commands, objectives and other contents of the source program are merely translated into machine-

readable code.” The different views of the Karn and Bernstein courts reflect the same questions raised by linguists like Brownson and Bar-Hillel, namely is computer code expressive or functional.

Both Karn and Bernstein were faculty members at U.S. universities who used encryption examples to teach computer science students about programming. Karn was permitted to export his textbook, but he was prohibited from exporting a floppy disc that contained a verbatim copy of the book. The only difference was that one was digital and the other was on paper (Camp & Lewis, 2001). However, in *Reno v. ACLU* (1997), the Supreme Court held that discrimination by media type was unconstitutional. An opinion delivered by Justice Stevens found that no distinction existed because of the medium used to communicate ideas. In reference to the Internet, which like a floppy disc is digital, he stated “that our cases provide no basis for qualifying the level of First Amendment scrutiny that should be applied to this medium.” He also referred to the district court’s opinion that the Internet is “the most participatory form of mass speech yet developed” and is therefore “entitled to ‘the highest protection from governmental intrusion.’”

Around this time, the rapid growth of the Internet led most academic publishers to stop issuing computer discs with textbooks. Instead, they posted examples on websites. However, because of the global nature of the Internet, the posting of encryption code on websites fell under the same export ban on encryption code as computer discs. In *Junger v. Daley* (2000), a university professor challenged a government ruling that he was not allowed to post encryption code on his website, even though his textbook containing the same code could be exported. In that case, the court held that computer code was protected by the First Amendment “[b]ecause computer source code is an expressive means for the exchange of information and ideas about computer programming.” The court also found that even if the code is primarily functional in nature, it is still protected by the First Amendment under *Roth v. United States* (1957), in which the Supreme Court stated that “ ‘all ideas having even the slightest redeeming social importance,’ including those concerning ‘the advancement of truth, science, morality, and arts’ have the full protection of the First Amendment.”

Another issue that was not addressed in the aforementioned cases is the role of encryption code in promoting the constitutionally protected free speech of others. Many countries suppress free speech as a way to control their citizens, to maintain state secrets, and to cover up human rights abuses. Organizations like Amnesty International rely on “encryption to protect their files and communications from seizure and interception by the governments they monitor for abuses” (Madsen, Sobel, Rotenberg, & Banisar, 1997).

The ability to disseminate and discuss cryptographic code has important value in protecting the First Amendment rights of American human rights workers who are living abroad. In *Broadrick v. Oklahoma* (1973), the U.S. Supreme Court held that litigants “are permitted to challenge a statute not because their own rights of free expression are violated, but because of a judicial prediction or assumption that the statute’s very existence may cause others not before the court to refrain from constitutionally protected speech or expression.”

The fact that these human rights organizations are operating in other countries does not diminish the First Amendment rights of the plaintiffs, who were U.S. citizens developing and disseminating code from within the United States. In *Yahoo!, Inc. v. La Ligue Contre Le Racisme* (2001), a U.S. company was convicted in a French court for disseminating information in France that violated French law, namely Nazi memorabilia. However, because the publication originated in the U.S., the U.S. District Court for the Northern District of California held that while “first amendment protections do not apply to all extraterritorial publications,” protections for “actions in the United States” do apply.

The development of “dark web” tools, like the Onion Router and the TOR browser, was funded by the U.S. Naval Research Laboratory in partnership with the Free Haven Project, “to promote unfettered

access to the internet in locations where online censorship was heavily enforced or where the threat of persecution for those who sought access to locally illegal information was prohibitive” (Moore and Rid, 2016). Although often vilified in movies like *Unfriended* and *Nerve*, TOR’s developers continue to focus on protecting journalists and human rights activists (Zetter, 2017). Not only do these dark net tools continue to play an important role in global free speech, they also enjoy the same legal protections.

Having established that computer code is speech deserving of First Amendment protection, the next question is whether the government has a compelling interest to regulate that speech. Clearly, cryptography can play an important role in national security concerns, such as drug trafficking and terrorism (Ferrera, 2004), but in cases where the courts have decided for the plaintiffs, the artistic and educational value of computer code outweighed this state interest. Cryptography also has important commercial value protecting trade secrets, banking records, and digital content, such as games, music, and movies. More importantly, it has a social value in protecting the free speech and free association of individuals and organizations, preserving the human rights and dignity of vulnerable populations, and preserving a free press.

SOLUTIONS AND RECOMMENDATIONS

American security is better served with unbreakable end-to-end encryption than it would be served with one or another front door, backdoor, side door, however you want to describe it. - Former CIA Director, General Michael Hayden (2016)

Arquilla and Ronfeld (1993) of the U.S. Naval Postgraduate School long predicted that “widespread multi-organizational networks that have no particular national identity” would attempt to undermine civil society. “A netwar may focus on public or elite opinion, or both,” they explained. “It may involve public diplomacy measures, propaganda and psychological campaigns, political and cultural subversion, deception of or interference with local media, infiltration of computer networks and databases, and efforts to promote dissident or opposition movements across computer networks.”

Twenty-five years later, social media is being used to promote authoritarianism, populism, and nationalism. Facebook and WhatsApp have become the de facto tools used by hate groups to encourage genocide in Africa, India, and Southeast Asia. Nation states have responded by attempting to regulate Internet discourse, undermine encryption, and expand surveillance.

In an effort to stem the tide of state overreach and protect against “netwars” and psychological campaigns, various stakeholders ranging from hacktivists to government agencies have developed computer programs that use open source and free cryptography tools to protect anonymity and bypass censorship. One such tool is the Onion Router, more commonly known by its acronym TOR, which has become virtually synonymous with the dark web. The explosion of online surveillance in the form of “Big Data” and machine learning over the past decade, along with massive data breaches that have cumulatively exposed the personal information of billions of Internet users, has led more people to seek privacy protections, including dark web tools. For instance, following the revelations by Edward Snowden of mass surveillance by the U.S. National Security Agency (NSA), TOR saw the number of daily users spike to nearly 6 million (see Figure 1).

Corporations are also taking on a greater role. On October 24, 2018, Apple’s CEO Tim Cook addressed the European Parliament, thanking Europe in taking a leading role through the General Data Protection Regulation (GDPR) and encouraging other parts of the world to follow suit. Cook argued that

Figure 1. The number of daily TOR users spikes in May 2013 following Edward Snowden's revelations of mass surveillance

Source: Used with permission from The Tor Project, Inc. under Creative Commons Attribution 3.0 United States License.

privacy was a “fundamental human right” and defended his company’s use of encryption to protect its customers (Cook, 2018). Despite pressures from governments to break encryption or provide back door access to communications, more companies have followed Apple’s lead in encrypting mobile devices, computers, and applications. Google and Facebook have embraced the Signal messaging protocol, an end-to-end encryption protocol developed by the non-profit Open Whisper Systems, as the default for Google Allo, Facebook Messenger, and WhatsApp (Cohn-Gordon et al., 2017). And new forms of encryption involving blockchain technology are being developed to protect sensitive information, such as health records, and preserve user privacy (Castaldo and Cinque, 2018).

Despite the clear benefits of protected communications in preserving privacy and human rights, some governments see encryption as a threat to national security and safety, typically citing the use of the dark net and encrypted messengers by terrorists, pedophiles, and criminal hackers. In 2018, ministers representing the Five Eyes nations (Australia, Canada, New Zealand, the United Kingdom, and the United States) met in Australia to discuss ways to combat “certain encryption designs” used to evade law enforcement. They urged “service providers to voluntarily establish lawful access solutions” or back doors to their products (Statement of Principles on Access to Evidence and Encryption, 2018). Shortly afterward, the Australian Parliament passed anti-encryption legislation titled the *Telecommunications and Other Legislation Amendment Act 2018* that requires companies to create back doors when requested. It immediately resulted in a flight of customers from the Australian tech sector (Crozier, 2019). One technology investor described Australia as “the place least welcoming to cybersecurity practitioners in the world” (McLean, 2019).

The exceptional access debate renews a defunct attempt by the NSA in the 1990s to introduce a “Clipper Chip,” ostensibly an encryption device that secured telephone communications. If implemented, a copy of the encryption keys would have been held in escrow to be used by law enforcement to wiretap select phones. However, researchers found that securing the keys in a centralized location was not only technologically challenging and expensive, it introduced security vulnerabilities that potentially undermined all secure communications (Abelson et al. 1997). For instance, the keys could be compromised by malicious insiders or through a cyberattack. The proliferation of encrypted devices since the 1990s

has only compounded the potential cost and challenges of implementing exceptional access (Abelson et al. 2015). Moreover, American companies have long argued that they would be placed at a competitive disadvantage to foreign competitors not bound by exceptional access requirements (Levy, 1994) and that only by relaxing encryption export controls in the late 1990s was the United States able to give birth to Amazon, eBay, and other firms that came to dominate global e-commerce.

The impact of Australia's anti-encryption legislation remains to be seen. However, given that the largest technology companies, including Apple, Facebook, and Google, are US-based, their underlying computer code, including encryption designs, will continue to enjoy protection under the First Amendment. Moreover, as noted in *Yahoo!, Inc. v. La Ligue Contre Le Racisme* (2001), that protection is extraterritorial if the service is provided from US-based computer networks.

Finally, the borderless nature of the Internet makes the regulation of encrypted communications nearly impossible to enforce. Technology companies will simply relocate to favorable jurisdictions, causing economic harm to countries with strong anti-encryption regulations. Brantly (2017), a Cyber Policy Fellow at the U.S. Army Cyber Institute Combating Terrorism Center argued that removing encryption from export bans in the early 1990s "was pivotal to the expansion of the internet because it made possible secure online commerce and the protection of communications and data." If the United States were to abandon its protection of computer code, and encryption in particular, it "would result in billions in lost revenues and undermine many of the core technical communities at the heart of the modern digital economy." Regulations seeking to ban or break encryption are misguided at best, he claims. Such regulations would simply increase the security risks for law-abiding citizens, while pushing criminals further underground and, by extension, making them more difficult to monitor. "Code, or the logical constructs within which encryption is implemented, is deliberate, and it functions to achieve software goals and objectives," Brantly notes. "From a technical perspective, the addition and manipulation of code that would be necessary to create backdoors undermines security."

FUTURE RESEARCH DIRECTIONS

The protection of computer code under the U.S. constitution has far reaching implications, as the world's largest technology companies are U.S.-based. However, that will not always be the case. As more technology companies emerge from other parts of the world, researchers will need to consider how to better harmonize the laws that govern computer code and the Internet. For instance, can members of the Five Eyes circumvent domestic laws by locating surveillance in a member state that does not have a Bill of Rights, like Australia? European law has already conflicted with U.S. law in *Yahoo!, Inc. v. La Ligue Contre Le Racisme*. Similarly, the GDPR is forcing companies in the U.S. to comply with European privacy regulations. Managing these conflicting laws and regulations will continue to pose challenges as lawmakers and regulators introduce new constraints.

Another important consideration is how regulations and laws have impacted innovation. For instance, First Amendment protection of computer code has been a driver of innovation that contributes to U.S. dominance in information technologies (Brantly, 2017). Will proposed regulations against encryption in other countries where computer code is not protected discourage innovation and entrepreneurship in the tech industry? Future research should consider the economic value of U.S. free speech protections of computer code and how to measure the economic impact of reversing these protections. For instance, the Information Technology and Innovation Foundation (ITIF) estimated that U.S. cloud computer companies like Google and IBM lost between \$22 billion and \$35 billion because of Edward Snowden's

NSA surveillance disclosure as companies shifted contracts away from the United States to companies in countries that promised to protect privacy, such as Switzerland and Germany (Castro, 2013).

CONCLUSION

Computer code and, by extension, cryptography are forms of speech protected by the First Amendment of the U.S. Constitution. However, the courts have also held that computer code is a special form of speech that has both functional and expressive elements. In many ways, computer code is more like art than pure speech and it can be restricted when there is a substantial government interest in doing so. Such restrictions, however, must not be more burdensome than necessary to achieve that government interest.

Governments seeking to regulate of the Internet and undermine cryptography do so on the premise that steps are needed to counter terrorists, hackers, child pornographers, and drug cartels. Some corporations have opposed what they see as government overreach, because it would undermine the security and privacy of law-abiding citizens. For instance, the NSA developed surveillance tools that gave backdoor access to Microsoft Windows servers and personal computers. Although there is no evidence that these tools prevented terrorist attacks or exposed criminal organizations, they were later leaked and weaponized by state-sponsored criminal hackers to develop powerful malware that destroyed computer networks around the world (Nakashima and Timberg, 2017). The NSA exploits caused major disruptions to the British National Health Service, crippled shipping giants Maersk and FedEx, and resulted in widespread power outages in the Ukraine. The estimated cost of the damage was in the tens of billions of dollars.

A noble purpose is not enough to warrant efforts to undermine cryptography. Leaked NSA tools demonstrate that back doors and hacking tools can fall into the wrong hands and be deployed by criminal hackers and repressive regimes to undermine democratic values. And while some agencies like the NSA and Federal Bureau of Investigation (FBI) have sought to ban or undermine encryption, other U.S. government branches, such as the U.S. military and the National Science Foundation, have been important backers of encryption and privacy tools like TOR. This support, along with the legal protections afforded to computer code under the U.S. constitution, have allowed the United States to dominate technology industries. When consumers lose confidence in these protections, it undermines the standing of American companies. Snowden's immediate impact on the economy should be viewed as a warning sign to legislators of the risks of tampering with the protections that have allowed the Internet to grow and flourish.

Today, the dark web and virtual private networks (VPNs) are used to bypass censorship in Venezuela, Russia, and China, to protect whistleblowers and journalists, who increasingly face threats to their safety and freedom, and counter what privacy activists describe as the surveillance state. News organizations have set up TOR onion sites as drop boxes where whistleblowers can anonymously submit news stories and tips, while some, like The New York Times, have created onion versions of their regular websites that can only be accessed using specialized anonymity browsers to bypass censors and evade surveillance. In western countries, the surveillance state and large corporate data breaches have created suspicion among many Internet users who are turning to encrypted messengers, VPNs, and TOR to protect their online privacy, while activists who support these services hope to force governments and corporations to be more accountable.

KEY TERMS AND DEFINITIONS

Blockchain: An encrypted ledger that protects transaction data from modification.

Cleartnet: Mainstream websites that are indexed by popular search engines, like Yandex, Google, and Bing.

Dark Web: A part of the deep web that uses hidden services to promote anonymity and prevent unauthorized access.

Deep Web: Internet sites that are not indexed by mainstream search engines. It can include password protected networks, such as corporate networks, email, and subscription only newspapers.

Encryption: A form of cryptography that protects data from being viewed without a decryption key.

GDPR: The General Data Protection Regulation is a European regulation that governs the protection of data and right to privacy of European citizens and residents.

Onion: A hidden Internet domain that disguises a site's true Internet (IP) address. Onion domains are accessed using TOR, usually through a specially designed Internet browser.

TOR: The Onion Router is an Internet protocol that uses multiple encrypted relays to protect user anonymity.

The TOR Browser: An Internet browser that is specially designed to use TOR to access both dark web and cleartnet sites.

Virtual Private Network (VPN): A remote server that creates an encrypted connection between the client and server to protect access.

Cybersecurity Legislation

Christopher Thomas Anglim

University of the District of Columbia, USA

INTRODUCTION

Nations throughout the world use cyberspace legislation to protect their cybersecurity and control criminal activity on the Dark Web. The Dark Web consists of underground websites and databases that are accessible anonymously using “The Onion Router” (TOR). Development of the technology operating TOR has frequently been attributed to the US Naval Research Laboratory. TOR protects the user’s identity by routing ordinary location services and Internet Protocols (IPs) through several different nations. TOR is an example of a darknet, which is a closed, private network that operates on the more conventional Internet Protocols. Darknets bypass the TCP/IP to ensure anonymous, essentially untraceable global networks.

The US government had intended to use TOR to provide the means for activists in nations with repressive governments to communicate with each other, without their government becoming aware of their activities. TOR has, however, become a form of contemporary technology that provides criminals with swift and often anonymous means to move funds and goods to enrich themselves through a wide variety of illegal activities such as hosting malware, selling illicit drugs, disseminating child pornography, arranging for contract killings, conducting terrorist acts, and laundering money.

This chapter explains the role of the legislature on all levels in controlling criminal behavior on the Dark Web, including the purpose of cybersecurity legislation, different approaches legislation, and the benefits and limitations of the legislative approach. In the United States, Congress continues to consider federal legislation intended to control the widespread criminal behavior that occurs on the Dark Web, such as the sale and distribution of drugs, illegal weapons, and child pornography. This chapter begins with an introduction that explains the purpose behind legislation. This followed by the Background section, which provides an overview on the topic of Legislation and the Dark Web, the purpose of such Legislation. Because this topic involves the balancing of basic rights and duties, the section also discusses the constitutional issues involved. Much of the chapter deals with Congressional action to date on the Dark Web and what Congress still needs to do on this topic. The Chapter then discusses legislative action taken on the state level, the international level, and legislative action that other nations have taken. The chapter concludes with recommendations for creating a legislative regime that seeks to both control criminal behavior on the Dark Web and ensure that the Dark Web is available for those who use need it for legitimate purposes.

Understanding Legislation as Lawmaking

Legislation is law as enacted by a legislative body after it has considered a specific measure. Laws enacted by Congress, a parliament, a state legislature, or a city council are examples of legislation. In the American system, legislation usually becomes law after being approved by an executive (such as the President, Governor, or Mayor) or if the legislature overrides the executive’s veto.

Legislation reflects policy considerations, meaning that it is subject to political concerns and preferences. The executive branch implements legislation and the judiciary reviews legislation. All laws require balancing between the individual's right to privacy and protecting the public's right to be protected. Liberty rights, including privacy rights are not absolute. These rights are balanced by the rights of other individuals and society. For nearly 30 years, legislatures on the local, state, and federal government have sought to prohibit certain types of behavior using computers as "cyber-crimes". This means that a government will prosecute individuals for violating the law and has imposed specific sanctions (such as fines and prison terms) for these violators.

As a very new type of law, cyberspace law remains a work in progress. While the principles of cybersecurity law are derived from the law governing other legal areas, not all of these precedents are designed to fit the current reality of cybersecurity. The Dark Web, especially, poses a large number of legislative challenges. These involve difficult issues of balancing the protection of free speech rights of individuals versus the need to protect the community from the online trade in a whole variety of illegal goods and services. Some of the many challenges in drafting cybersecurity law include that criminals freely use technology to maintain anonymity on the Web. This allows them to evade law enforcement with relative ease. The need for legislative action in controlling criminal activity on the Dark Web became particularly apparent as law enforcement agencies uncovered such sites as the "Silk Road", which were anonymous online markets for illicit and illegal goods. These online black markets allowed buyers to purchase illegal drugs and the transactions in bitcoin and conduct transactions anonymously, using "dummy" transactions to conceal the connection between buyers and sellers. By so doing, the Silk Road evaded The US's most advanced electronic surveillance technology. The site operated from 2011 until the Federal Bureau of Investigations (FBI) curtailed its operations in 2013. While in operation, the Silk Road amassed an estimated \$1.2 billion in revenue. Other illicit sites such "Pandora Market" and "Hydra Marketplace" followed the Silk Road Model.

The situation has worsened grew worse over time. At the time law enforcement authorities force the site, Alpha Bay to close in 2017, that site had 200,000 users, 40 vendors, and was ten times the size of Silk Road. Alpha Bay indicated that buyers and sellers were scaling up their operations on the Dark Web.

At the same time, hackers operating in the Dark Web stole a large amount of private customer data from Equifax, a major consumer credit reporting agency. The hackers then demanded 600 Bitcoins (about \$2.5 million) in exchange for the sensitive financial information of the 143 million people. The way that these criminals were able set up such a secret, untraceable criminal enterprise at such a massive scale led policymakers to doubt whether law enforcement had sufficient authority and technology to contend with the illicit Dark Web activities (Ghappour, 2017).

The Dark Web has also become a major marketplace of counterfeit and stolen medicine. Criminals have found that the return on investment of such products has been very high. This trade in harmful, useless, or expired medicines has tragically led to the deaths of many who relied on them.

BACKGROUND

Overview

Cyberspace is a virtual computer world. More specifically, is an electronic medium used to form a global computer network to facilitate online communication. This chapter focuses on recent cybersecurity legislation, seeks to determine the effectiveness of specific cybersecurity legislation, and present

possible alternative policy alternatives. This chapter focuses on: 1) the scope of cyberspace legislation, 2) the rationale for cyberspace legislation, 3) arguments in favor of certain cyberspace legislation, 4) arguments against certain cyberspace legislation, 5) the evolution of cybersecurity legislation, 6) the impact and effectiveness (or likely impact and effectiveness) of this legislation and 6) what additional cybersecurity legislation might be necessary, both on the state and federal level. Specifically, this chapter discusses legislation intended to control criminal behavior on the Dark Web. One should note that there are three types of law: statutory law (law passed by a legislature), case law (law promulgated by the courts), and administrative law (law issued by an administrative agency). In terms of scope and definition, cyberspace legislation is law on cyberspace passed by a legislature (such as Congress on the federal level and state legislatures on the state level). Legislation does not become binding and effective until signed by the jurisdiction's chief executive (such as the President of the United States or the Governor of an American state).

Cyberspace law is intended to both control criminal behavior on the deep web, while also protecting legitimate speech and legitimate business transactions. In efforts to control criminal behavior on the Dark Web, there is the possibility that legislation directed against the Dark Web may also adversely affect the flow of information among peoples living in oppressive regimes, where information is heavily censored. In addition, the military, corporate whistleblowers, and victims of abuse need access to the Dark Web to both maintain their confidentiality while exercise their free speech rights.

A recent British study analyzed several websites accessible through TOR and found that 1,547 out of 2,723 live sites had "illicit content" (Moore & Rid, 2016). Usually this content included "drugs, illicit finance and pornography involving violence, children and animals" (Moore & Rid, 2016). The researchers concluded that "more than 50 per cent of what's hosted [on TOR] is illegal and illegitimate", while other reports found that an even higher representation. The researchers explained that the discrepancy is due to the fact that they used a restrictive definition of illicit content (McGoogan, 2016). The actual representation, however, may be even higher because the researchers did not review every Dark Web site because of how TOR operates (Moore & Rid, 2016). Nonetheless, the researchers presented much evidence that the Dark Web facilitates criminal behavior on a massive scale. Further, the researchers show that law enforcement agencies have serious difficulties in identifying and prosecuting the accused.

Legislating against criminal behavior on the Dark Web entails the difficult objective of ensuring an equitable balance between individual liberty and public safety. The key issues include: 1) Who should police the Dark Web and what authority should they have?, 2) What is the scope of authority of those who police the Dark Web?, 3) What are the benefits of an international agreement and organization to police criminal behavior on the Dark Web.

Browsers on the Dark Web provide users complete anonymity, which help criminals conduct their trades largely undetected. While potential enforcement options exist, each have drawbacks. Some commentators argue that crime on the Dark Web can only be truly eradicated by completely eliminating the entire Dark Web (Haasz, 2016). James Clapper, the former Director of the National Security Agency is one of those who favors eliminating online anonymity because America's adversaries use it to direct attacks against the United States and its allies throughout the world.

Despite the risk involved, there is a large volume of both legitimate and illicit goods and services bought and sold on the Dark Web, with an always available supply of willing sellers and willing buyers (Haasz, 2016). The only feasible solution, then may be to enact effective legislation crafted to deter crime and improved enforcement of criminality on the Dark Web.

Michael Chertoff, a former Secretary of the Department of Homeland Security during the George W. Bush administration, well described the challenges of drafting legislation intended to protect against criminal behavior on the Dark Web:

Creating policy to address the Dark Web requires an understanding of the benefits and risks of anonymity and of an open internet. Rash and sweeping legislation has the potential to encroach on civil liberties and to be a nightmare to enforce. On the other hand, not addressing the Dark Web will allow illicit activities to persist unabated. It is impossible to regulate the Dark Web in isolation; any regulations must be applicable to the internet as a whole and will thus affect Surface Web users, Deep Web researchers, and Dark Web criminals alike (Chertoff, 2017).

Defining the Purpose of Cybersecurity Legislation

Cybersecurity legislation reflects the legislature's intent to protect the American people against cyber-criminals who seek to exploit perceived and actual cyber-vulnerabilities. These cyber- vulnerabilities exist within the critical infrastructure information environments worldwide. Cyber-vulnerabilities include flaws in computer systems or set of procedures that could create a threat. Threats to the international cyber infrastructure continues to escalate and diversify. Thus, these vulnerabilities present ubiquitous challenges to governments, businesses, political organizations, and individuals. The criminal attackers are often motivated by a wide variety of differing purposes, including seeking military intelligence, diplomatic or commercial espionage, cybercrime, or achieve political advantage. Legislators, then, must consider these threats in seeking to draft such cyberspace legislation.

Constitutional Concerns Involved With Federal Cybersecurity Legislation

As with all federal legislation in the United States, the legislation against criminal activities on the deep web must be comply with relevant provisions of the US Constitution. Of these provisions, the Fourth Amendment is particularly important. The Fourth Amendment protections against the unreasonable search and seizure, by any government entity, of one's person or one's property by requiring that a warrant based upon probable cause be issued by a neutral magistrate. A 'search' occurs when the government infringes on what society views as a reasonable expectation of privacy. Courts recognize that certain areas such as an individual's home have the highest level of privacy protection. The Fourth Amendment, for example, strongly protects against a warrantless search of a person's home, while providing much less protections in other areas. Contemporary technology greatly complicates privacy protection under the Fourth Amendment particularly because American law has not kept pace with the changing social expectations of privacy. For many contemporary Americans, their most smartphones and laptops hold their most confidential information and could cause much damage if they fall into the wrong hands (Ghappour, 2017).

The American Approach to the Statutory Law of Cyberspace

For over two decades, US cybersecurity policy approach has developed largely based on self-regulation and incremental improvement, following Thomas Kuhn's "change theory". Under this theory, a change from one paradigm to another occurs when sufficient issues occur under the current paradigm develop, forcing reasonable observers to question the existing order. It remains controversial as to whether this

interpretation of change theory is sufficient to meet current need to ensure cybersecurity due to the dynamic challenges posed by nature of illicit behavior on the Dark Web. Nonetheless, change theory continues to form the basis of existing American federal Cyberspace law.

Congressional Action on Cybersecurity

As the national legislature, Congress has a critical role in articulating and protecting federal cybersecurity. Most federal cybersecurity statutory law was enacted prior to 2002. Because of several obstacles in crafting effective legislation on criminal activities on the Dark Web, Congress has enacted very little legislation on that topic. Nonetheless, Members of Congress continue to be highly interested in the topic, as evidenced by the large amount of debate and legislation introduced on the topic. The question is, then, why has a major federal statute not been enacted on criminal behavior on the Dark Web. What legislation Congress has actually enacted delegates much of the federal legal authority over activities on the Dark Web to certain federal agencies, which regulate these activities through their rulemaking and enforcement powers. This delegation is justified in part because these agencies have the expertise needed to make such regulations.

In 2002, Congress enacted the Homeland Security Act (HSA, 2002) and the Federal Information Security Management Act (FISA, 2002). HSA is foundational legislation that stipulates the roles and responsibilities for federal cybersecurity protection. It also required agencies to develop and implement programs to secure their information and information systems. In 2004, Congress enacted the Federal Information Security Modernization Act (FISMA, 2014). This modified the original 2002 statute to clarify and update the responsibilities and authorities of DHS and the US Office of Management and Budget (OMB) to protect federal agency information security. In recent years, Congress has considered legislation to expand DHS's cybersecurity authority. In 2014, Congress enacted the National Cybersecurity Protection Act of 2014 (NCPA, 2014), which codified the National Cybersecurity and Communications Integration Center (NCIC) within DHS to interface and share cybersecurity information across federal and non-federal entities (including the private sector). Also in 2014, Congress enacted the Federal Information Technology Acquisition Reform Act (FITARA) of 2014 to expand the authority of chief information officers (CIOs) and deal with issues including risk management, IT training, and acquisition/procurement. In 2015, Congress passed the Cybersecurity Information Sharing Act (CISA) (CISA, 2015) which authorized the US Department of Homeland Security (DHS) to exchange threat information with the private sector. Congress, at that time, however, declined to grant DHS complete authority over cyberspace. It recognized the authority of other agencies over cyberspace issues and allowed them to continue asserting control over cybersecurity in the civilian sector. Several Congressional committees claim jurisdiction over DHS and argue that they should be the committee that should have jurisdiction to protect federal cyberspace policy.

Congress enacted CISA (CISA, 2015) to encourage federal government and private industry to share information, through DHS, by providing liability protections for private individuals and organizations that share relevant information with DHS. CISA also requires all federal non-defense agencies to implement EINSTEIN, a DHS program that detects and blocks threats to federal networks.

On December 12, 2017, President Barack Obama signed the National Defense Authorization Act (NDAA) for Fiscal Year 2018 (NDAA, 2017). This statute launched several cybersecurity initiatives and new rules and programs on information security, including formally prohibiting use of Kaspersky Lab software (NDAA, § 1634, 2017), granting the President authority to define cyberwar" (NDAA, § 1633,

2017), and mandating the Department of Defense to evaluate and reorganize its internal organizational structure to implement cybersecurity and related missions (NDAA, §§ 1641, 1644, et al., 2017).

On August 13, 2018, Congress enacted the National Defense Authorization Act (NDAA) for Fiscal Year 2018, which authorized appropriations and US Defense Department policies on issues such as cybersecurity and the Dark Web. Some privacy advocates have argued that some federal cybersecurity statutes may encourage more individuals to rely on the Dark Web. Congress, under the Trump Administration, for example, passed legislation to strengthen the federal surveillance power over the computer behavior of Americans on the basis of national security. In March 2018, President Trump signed into law the “Clarifying Lawful Overseas Use of Data Act (CLOUD, 2018)”, which abolished an Obama-era privacy rule that prohibited Internet Service Providers (ISPs) from sharing user information without their consent. Privacy advocates argued that this may encourage more Internet users to rely on the Dark Web to protect their identity.

A similar debate, also in the Spring of 2018, occurred when Congress voted to approve legislation to discourage advertising for prostitution on the Internet by making websites more responsible for the ads and postings that appear on their sites. Congress did this by amending Section 230 of the Communications Decency Act of 1996 (which is intended to protect free speech on the Internet) (CDA, 1996). Some members of Congress supported amending the section after the adult-services website, backpage.com, successfully used the section to defend itself in court for posting ads for child prostitution. Proponents of the law raised the case of Desiree Robinson, a 16 year old young woman, who aspired to be an Air Force doctor. She was killed by a man who paid for sex with her after seeing an ad paid by Desiree’s pimp was placed on backpage.com. Some privacy and free speech groups argued that this decision would make involuntary sex workers more vulnerable by forcing prostitution increasingly into the Dark Web. The became law and specifically provided that Section 230 does not prohibit enforcement against providers and users of interactive computers and services, of federal and state criminal law relating to sexual exploitation of children or sex trafficking (Allow States and Victims to Fight Online Sex-Trafficking Act, 2017).

While there is some federal statutory law applicable to Dark Web, these statutes were never specifically drafted to meet the special challenges of the Dark Web. The Dark Web, for example, facilitates hacking and aids hackers. Hackers often obtain their malware from other hackers, or seek to extort money through ransomware. In cases such as these, the Computer Fraud and Abuse Act (CFAA), has been interpreted as prohibiting hacking a form of trespassing on, unauthorized accessing of, and damaging computers in interstate or international commerce. The CFAA also bars trafficking, unauthorized computer access, and computer espionage. While these U.S. statutes may adequately cover hacking, they do not address the issues of anonymous online users. They also do not effectively prosecute Dark Web criminal activities emanating from outside the United States, where most cybercrime directed against the United States originates from. Because of this, effective international action and cooperation is essential in addition to effective, well-drafted US federal legislation to confront criminal behavior on the Dark Web (Chertoff, 2017).

State Cybersecurity Legislation

Cybersecurity threats have serious implications for government security, economic prosperity and public safety. State governments address cybersecurity issues by actions such as: 1) requiring government or public agencies to implement security practices; 2) offering incentives to cybersecurity; 3) providing

exemptions from public records laws for security information; and 4) creating cybersecurity commissions, studies or task forces.

State Efforts to Promote Cybersecurity Training and Education

Like the Federal government, state governments address cybersecurity through various approaches. On the state level, these initiatives include requiring government or businesses to implement security procedures or security audits, creating studies or task forces, and promoting the cybersecurity industry or training for technology skills.

States address cybersecurity through various initiatives, including increasing funding for improved security measures, requiring government agencies or businesses to implement specific types of security practices, increasing penalties for computer crimes, and addressing threats to critical infrastructure. In recent years, most state legislatures have deliberated cybersecurity or data security, while some governors issued executive orders.

Many of these bills considered matters related to: 1) security practices and protection of information in government agencies, 2) exemptions from state Freedom of Information of Public Records acts for information that could jeopardize security of critical information or infrastructure, and 3) cyber/computer crimes.

These statutes are intended to: 1) Improve government security practices, 2) Create commissions, task forces and studies, 3) Provide funding for cybersecurity programs and initiatives, 3) Target computer crimes, 4) Restrict public disclosure of sensitive security information, and, 5) Promote workforce, training, economic development.

Cyberattacks Against United States Targets

Numerous diverse cyberattacks against US individuals and entities have ranged from corporate hacks and credit-card scams to Russian hackers and government breaches. Many of these incidents have been massive and have the potential to cause widespread devastation if successful. To prepare for the possibility of such attacks or to effectively respond to such attacks if they should occur, state and federal legislators have made cyber-safety a major legislative priority.

Much of America's cybersecurity legislative framework had been developed by 2002, well before criminal activity on the Dark Web became so prominent and pervasive. Legislative action has rapidly expanded since that time because of the continuing, changing, and growing threat to American cybersecurity, including that emanating from the Dark Web. In 2017, Congress considered over 240 federal cybersecurity bills. Once in power, the Trump Administration very quickly responded to the threat to American cybersecurity by issuing Executive Order 13800 ("Strengthening Cybersecurity of Federal Networks and Critical Infrastructure") (EO, 2017, Jul. 12) to provide more stringent data regulation and to enhance American defenses against cyberterrorism.

RECOMMENDATIONS

The American Federal cyberspace statutory framework remains largely underdeveloped. Much of this is due to the fact that there is a lack of consensus as to the legislative approach to be taken against criminal activity on the Dark Web. Although Congress has deliberated several different bills on the subject, it

remains challenging to craft effective legislation that both prohibits illicit activity on the Dark Web and does no beneficial, useful, and lawful activity that also occurs on the Dark Web. Both state legislation and caselaw on the criminal activity on the Dark Web should help inform further development of federal legislation on the subject. Congress continues efforts to develop comprehensive federal legislation, appropriately designed to protect individual Americans and American entities in cyberspace. Federal legislation, thus, should have the following provisions that both to protect against criminal behavior on the Dark Web and protect against individual liberty.

1. The purpose of the legislation and the definition of the offenses and penalties pertaining to the criminal activities on the Dark Web.
2. Contain language to help protect freedom of speech, creative innovation, and legitimate economic transactions through the Internet.
3. Clearly delineate the duties and responsibilities of government agencies charged with combatting criminal activity on the Dark Web.

Despite how federal law evolves in protecting against criminal activity on the Dark Web, it must do the guarantee four key objectives: 1) protect the civil rights, civil liberties and privacy rights of Americans, 2) maintain a lawful means of accessing encrypted data to facilitate criminal investigations, 3) gather effective, relevant intelligence, and 4) protect Americans and American entities against criminal activity on the Dark Web.

It is also be instructive to see how other nations draft legislation on the Dark Web. Germany, for example, is considering criminalizing the provision of Dark Web infrastructure providers and making such actions punishable by three years in prison. Civil libertarians and journalists are among those who oppose this legislation.

CONCLUSION

All Legislators (whether serving on the international, national, state, or local levels) are concerned about criminal activity on the Dark Web and the harm that individuals and organizations could suffer as a result of this behavior. The legislator's work is challenging because 1) he or she must balance the needs of individual liberty and privacy versus the need to protect public safety, and 2) the Dark Web is an international phenomenon, which transcends national boundaries, national laws, and national enforcement. Thus, in addition to well-drafted national legislation, then, there must also be both effective international legal standards and international cooperation to combat the criminal use of the Dark Web.

KEY TERMS AND DEFINITIONS

Congress: A national legislative body, especially that of the US. The US Congress, which meets at the Capitol in Washington DC, was established by the Constitution of 1787. It is composed of the Senate and the House of Representatives.

Cyber-Vulnerabilities: A flaw in a computer system that can make the system vulnerable to attack. A cyber-vulnerability may also refer to any type of weakness in a computer system itself, in a set of procedures, or in anything that leaves information security exposed to a threat.

Cybercrime: Any criminal action perpetrated primarily through the use of a computer.

Cybersafety: Is the safe and responsible use of Information and Communication Technologies (ICT). NetSafe's approach to cybersafety is founded on: Maintaining a positive approach about the many benefits brought by technologies. Encouraging the public to identify the risks associated with ICT.

Cybersecurity: The state of being protected against the criminal or unauthorized use of electronic data, or the measures taken to achieve this.

Cyberspace: The domain of the worldwide technology environment.

Dark Web: The deep is a small part of the deep web that has been intentionally hidden and is inaccessible through ordinary web browsers. Internet users are unable to access this portion of the web without using browsers dedicated to providing absolute anonymity to users. The dark web has become a haven for criminal activity.

Deep Web: The part of the web not a part of the surface web. It includes content inaccessible through the use of a search engine. These include private servers that only those with permission may access, intranets utilized by a variety of organizations, or even typical social media pages that users wish to keep concealed from the general public.

Legislation: Law enacted by a legislature.

Legislature: A body of individual persons empowered to legislate; specifically, an organized body authorized to make laws for a political entity such as a nation, state or province, or a city.

Surface Web: Web content that can be indexed by ordinary search engines such as Google or Yahoo.

International Context of Cybercrime and Cyber Law

Tansif Ur Rehman

University of Karachi, Pakistan

INTRODUCTION

It is clearly evident that as people become more dependent on technology, they become easier targets of cybercrime, as it also could evolve to bring about new problems. It is also important to realize to what extent it is understood by common people that either they are really a victim or can be the victim of a cybercrime.

This research includes significance as well as international aspects of cyber laws, initiatives by the EU, USA, China, and the role of international forum for cybercrime. At the very least, it demonstrates the fact that cybercrime attacks are an almost routine form of criminality and most internet users are likely to face an attack on a daily basis.

OBJECTIVES

1. To highlight the significance of cyber laws.
2. To highlight the international aspects of cyber laws.
3. To discuss the initiatives taken by the EU, USA, and China regarding cybercrime.
4. To discuss the role of international forum for cybercrime.

BACKGROUND

Cybercrime has so advanced that it was reported in August 2018 during the Black Hat and Def Con Hacking Conference that, it was possible to even hack patients' vital signs, pacemaker, and insulin pumps in real time (Smith, 2018). Symantec, one of the leading software firms that operates antivirus and firewall packages, stated in their 'Internet Security Threat Report 2011' (published in 2012) that there had been an 81% increase in malicious attacks that they had identified, with an estimate of attacks being placed over 5.5 billion.

A Barkly sponsored survey of 660 IT companies and professionals by Ponemon Institute, USA (2018) 'State of Endpoint Security Risk' has revealed that 64% of organizations experienced successful endpoint attacks. This survey has also revealed zero-day and fileless attacks that cost millions to organizations, i.e. costs doubling for Small and Medium-sized Businesses (SMBs).

Cybercrime's pace globally is on a high rise. It is an offense that is even harder to identify and resolve as compared to traditional crimes in the international context. Cybercrime cells all around the world receives thousands of complaints on a daily basis.

DOI: 10.4018/978-1-5225-9715-5.ch028

Cyber criminals are honing their skills, while consumers remain unconcerned. Cyber criminals are innovative, organized, and far sophisticated (Hutchings, 2013). They employ their tools effectively, working harder, and focused to uncover new vulnerabilities as well as escape detection. The ICTs are opening a whole new world of opportunities for criminals and the risk remains largely unknown.

The protection against cybercrime largely depends upon the security culture adaptation by government authorities of every networked country, business organizations, and most importantly, every internet user. Prevention will always be the first and best line of defense along with radical changes in policing and legislation (Glenny, 2012). Education and awareness across the citizens will go a long way to prevent individuals against many types of cybercrime and will reduce pertinent risks (Lusthaus, 2012).

FOCUS OF THE ARTICLE

This article focuses on the significance, international aspects of cyber laws, initiatives by the EU, USA and China, and the role of the international forum for cybercrime. This research will also help to understand the computer-related crime advancement, and how to use it as defined within the premises of law in an international context.

CHARACTERISTICS OF CYBERCRIME

1. Scale
2. Accessibility
3. Anonymity
4. Portability or Transferability
5. Global reach

VARIETIES AND SKILLS OF CYBERCRIME

1. Hacking of Computers
2. Denial of Service Attacks (DoS)
3. Distributed Denial of Services Attacks (DDoS)
4. Malware
5. Spyware
6. Offense Relating to Data
7. Destroying, Disclosing, and Accessing Data
8. Misconduct in a Public Office
9. Phishing
10. Pharming
11. Hate and Harm

CYBER FRAUD

There are other crimes that use technology, i.e., fraud, which is sometimes known as cyber fraud when it is committed online (Yar, 2013). Fraud based behavior exists online as well as offline, but the internet now provides ample opportunities to use it in the form of a new tool (Ekblom, 2014). There is a wide difference regarding the victimhood of fraud. It could possibly range from buying a non-existent item from the internet to MNCs losing millions of dollars annually (Sandwell, 2010).

CYBERTERRORISM

A popular definition of cyberterrorism is the “intentional use or threat of use, without legally recognized authority, of violence, disruption or interference against cyber system, when it is likely that such use would result in death or injury of a person or persons, substantial damage to physical property, civil order, or significant harm” (Jones, 2005, p.4).

Terrorism is generally seen as an attack against the state’s interest, sometimes it even involves attacks against private industry. The term itself is easily understood, it consists of ‘cyberspace’ and ‘terrorism’ combination to produce the importance of terrorism that takes place either in, or through the internet.

Terrorists have used the internet, specially, from the last decade and this is perhaps a convenient way of reaching a large audience (Brenner, 2014). The main uses of the internet by terrorists are:

1. Propaganda
2. Fundraising
3. Information Dissemination
4. Secure Communication

SIGNIFICANCE OF CYBER LAWS

Yoshio Utsumi was the former Secretary General of International Telecommunication Union (ITU) from 1998 to 2006. ITU is a specialized agency of the United Nations. It is responsible for issues that concern Information and Communication Technologies. He accentuated the significance of immediate measures for security of cyberspace, Information and Communication Technology Systems (ICTs), and its infrastructure. As, the interlinking of business processes and economic activities through the use of information technology is increasing exponentially.

He further expressed his concerns regarding the instillation of consumer confidence in online activities like e-governance, commerce, telemedicine, trade, as well as hosting of various other applications. He also pointed out that cyber security is indispensable for the future development of economical as well as social activities worldwide.

According to Norton Cybercrime Report 2011, a cyber security firm, cyber crimes have increased dramatically over the years which cause the sufferings to 431 million victims globally or 14 victims every second. There are around one million cybercrime victims every day.

Findings by a research organization, Comparitech, Mr. Paul Bischoff (2018) claims that stock prices are adversely effected by data breaches. In case of a data breach, it can lead to around 0.5 percent decrease in a firm’s overall share in market.

A new study, conducted by Bromium and Dr. Michael McGuire, senior lecturer in criminology at the University of Surrey in England, presented at the RSA Conference 2018 in San Francisco has found that the cybercrime economy has grown to \$1.5 trillion dollars annually. Cybersecurity Ventures is world's renowned research company with regards to global cyber economy as well as cyber security. In their official annual Cybercrime Report 2017 they predicted that cybercrime will cost the world around \$6 trillion annually by 2021.

Cyber law can be termed as the carrefour of developing innovative technology and prescribed rule of conduct or action enforced by the controlling authority. Cyber law is an umbrella term which encircle a wide range of political and legal aspects related to the internet usage and ICT (Information and Communication Technology), which includes freedom of expression, online privacy, intellectual property, and jurisdiction, etc.

The escalation of cybercrime is so significant and impacting that cyber law has been a major concern of governments worldwide. Continuous development in cyber law tend to contend more definitive, safe, and uncluttered cyberspace. The development of regulated code of conduct for IT and other electronic medium related to it is an ongoing process to meet the evolving facets of cybercrime.

CYBERCRIME STATISTICS

According to Alvarez Technology Group (2018); Devon Milkovich (2018); and Patrick Nohe (2018) these are few of the most alarming cybercrime statistics:

1. 95% of breached records came from only three industries worldwide, government, retail, and technology.
2. There is a hacker attack every 39 seconds in US alone according to the study conducted by the Clark School at the University of Maryland, USA.
3. 43% of cyber attacks target small business. 64% of companies have experienced web-based attacks. 62% experienced phishing & social engineering attacks. 59% of companies experienced malicious code and botnets and 51% experienced denial of service attacks.
4. The average cost of a data breach in 2020 will exceed \$150 million according to Juniper Research data.
5. Since 2013 there are 3,809,448 records stolen from breaches every day.
6. According to the Q2 2018 Threat Report, Nexsuguard's quarterly report, the average distributed denial-of-service (DDoS) attack grew to more than 26Gbps, increasing in size by 500%.
7. Approximately \$6 trillion is expected to be spent globally on cyber security by 2021.
8. Unfilled cyber security jobs worldwide will reach \$3.5 million by 2021.
9. By 2020 there will be roughly 200 billion connected devices, which means more exposure to cybercrime.
10. 95% of cyber security breaches are due to human error.
11. Only 38% of global organizations claim they are prepared to handle a sophisticated cyber attack.
12. Total cost for cybercrime committed globally has added up to over \$1 trillion dollars in 2018.

TOP 10 COUNTRIES FACING CYBERCRIME

According to Sumo3000, Enigma Software Group, USA (2018), following are the top ten countries that are facing cybercrime. These 10 countries face around 63% of the total cybercrime committed across the globe.

1. USA (23%)
2. China (9%)
3. Germany (6%)
4. Britain (5%)
5. Brazil (4%)
6. Spain (4%)
7. Italy (3%)
8. France (3%)
9. Turkey (3%)
10. Poland (3%)

INTERNATIONAL ASPECTS OF CYBER LAWS

The advancement of internet has enabled users to access information which was a dream once, and the technology like Voice over Internet Protocol (VoIP) has revolutionized communication. One can access information without suffering barriers available in internet, no matter whether which country hosts it.

A specialized agency of the United Nations, responsible for issues concerning information and communication technologies is International Telecommunications Union. Information and communication streaming around the world is swift and smooth as never before. Although, physical border still has importance, but ones and zeros, bits and bytes flow with a continual change of places among countries freely. Cyber criminals avail this advantage and commit crimes on places other than where they are located. National supremacy is no more an issue for the transnational cybercrime.

The significance of respective issue made developing countries more concerned to cautiously build and deploy the security and trust. So, the benefits and advantages of ICTs can serve their citizen not only for commercial activities, but its application can be make useful at societal level such as health, education, and e-government, etc. International aspects of cyber laws encompasses:

1. To identify cybercrime threats and vulnerabilities and deploy solutions to secure ICT infrastructure for internet consumers and its application on different networks using pertinent technologies.
2. To support and work along with member states in gradual developments of laws and set exemplary legislation for internet services, internet security, its ethical issues, deterrence of cybercrime, data security, as well as privacy.
3. To increase security and make cyber environment as unattractive as possible to cyber criminal, so that confidence of consumer is enhance while using internet services and respective applications.
4. To develop hardware and software tools to promote and exchange best possible practices on ICTs security and related legitimate concerns in the respective areas.

INITIATIVES BY THE EU AND USA

The initiatives regarding cyber law by the United States of America are discussed below because of the role of USA as a global superpower in terms of technology and world's strongest economy in terms of nominal GDP, i.e. \$20.891 trillion (IMF, 2018). While, the European Union is a political and economic union of 28 member states, and accounts for being the strongest monetary union in the world with a nominal GDP \$19.14 trillion (ibid.). People's Republic of China is the third largest economy of the world after the US and the EU. It boosts for being a regional superpower as it has a nominal GDP of \$14.21 trillion (ibid.).

In almost all European countries, the European Union has implemented the rules and regulation on electronic trade and commerce through legislation and makes sure that non-member countries align their laws with the EU initiative.

USA's experience and knowledge in the field of legislation regarding cyber security is significant. The USA has organized and featured structure for consumers of ICT to report cybercrime against them. The foremost federal law enforcement agencies which are responsible for investigation of cybercrime at domestic level include:

1. United States Secret Service (USSS)
2. Federal Bureau of Investigation (FBI)
3. United States Postal Inspection Service (USPIS)
4. United States Immigration and Customs Enforcement (ICE)
5. Bureau of Alcohol, Tobacco and Firearms (ATF)

In almost all European countries, the European Union has implemented the rules and regulation on electronic trade and commerce through legislation and makes sure that non-member countries align their laws with the EU initiative.

USA's experience and knowledge in the field of legislation regarding cyber security is significant. The USA has organized and featured structure for consumers of ICT to report cybercrime against them. The foremost federal law enforcement agencies which are responsible for investigation of cybercrime at domestic level include:

Every state has offices for cybercrime monitoring agencies where crime can be reported conveniently. Every state office has a predefined contact information which is easy to access and cybercrime can be reported to the local office of concerned agency by even a phone call to an available duty complaint officer.

Every law enforcement agency headquarters are situated in Washington, D.C, where a number of law enforcing officers who are well trained and specialized in their particular fields are working vigilantly. Federal Bureau of Investigation and USA Secret Service, both have their head offices in Washington and are responsible for protecting forcible intrusion by cyber criminals. For most of the time, the aim of cyber criminals is either monetary gains or access to classified data. Generally, they are termed as hackers, i.e., they hack into legitimate computer networks.

Federal Bureau of Investigation in collaboration with National White Crime Complaint Centre, another US prominent agency, established Internet Crime Complaint Centre (IC3) in 2000. It is serving as a platform to receive cybercrime complaints, develop strategies, and refer cybercrime complaints to confront increasing cyber threats.

The IC3 has remarkably a positive staff culture regarding cybercrime victims where one can report crime because of their friendly reporting system which immediately make sure that concerned authori-

ties are notified and appropriate action against cyber criminal has been initiated. IC3 also makes sure that the central referral mechanism is intact for regulatory and law enforcement agencies at the federal, state, and local level.

Other Initiatives by the Government of United States Regarding Cybercrime

1. Online Copyright Infringement Liability Limitation Act - 1998
2. Digital Millennium Copyright Act - 1998
3. Uniform Computer Information Transactions Act - 1999
4. Internet Fraud Complaint Center (IFCC) (founded in 2000)
5. U.S. Computer Emergency Readiness Team (founded in 2003)
6. Controlling the Assault of Non-Solicited Pornography And Marketing Act - 2003
7. Proposed EU Directives on the patentability of computer-implemented inventions.
8. National Association of Attorney General's Computer Crime Point of Contact List.
9. Department of Homeland Security's National Infrastructure Coordinating Center.

INITIATIVES BY CHINA

The second largest internet users after USA are from the People's Republic of China. There are approximately 111 million internet users in this country. China reaps the advantages of technological growth, but at the same time while such a huge number of people were accessing internet, regulation as well as supervision from authorities were lacking. It caused a rampant growth in cybercrime, which include the spread of pornographic material, hate and harm content, illicit gambling, online frauds, etc.

Chinese authorities addressed the issues exemplary. They deployed surveillance and regulated their internet users, which not only mitigated the growth of cybercrime, but also left a positive growth on their e-trade.

Shenzhen, in southeastern China, is a modern metropolis, according to the statistics presented by the Shenzhen Association of Online Media and the China Internet Network Information Center (CINIC), there were 8.97 million internet users in Shenzhen by the end of 2015. The highest ratio nationwide, which is 83.2 percent of Shenzhen's total population, is on top of achieving success regarding online crimes and rapid spread of malicious and hazardous information by forming a cyber police force.

Cyber police in China has developed a system to patrol and keep active presence on online activities of users. When a user gets online, an icon which shows the presence of police department flashes on the user's screen. Whenever a user needs to contact for a cybercrime complain, he just has to click the respective icon, and can report to the immediate complaint officer in few minutes.

In a few months time, cyber police has been notified regarding online crimes by clicking icon that accumulated around 100,000 clicks, which include more than 600 consultation services on cybercrime legislation along with 1,600 reports of online criminal activities, out of which 235 have been forwarded for legal proceedings. The Ministry of Public Security has decided to establish cyber police in eight major cities of China after the success in Shenzhen.

Role of Chinese Cyber Police

1. Cyber police vigilantly patrol online, where cybercrime ratio is high to warn cyber criminals.
2. Internet users can easily access information regarding cyber legislation and understanding of complication of cyber criminal cases.
3. The cyber police force not only records the complain regarding cybercrime, but also assists online users about legal aspects concerning cybercrime.

INTERNATIONAL FORUM FOR CYBERCRIME

The invention of internet has created many possibilities and opportunities for artistic and literary creation. Although, we find traditional laws of copyright in physical world, but legislation for cyberworld in other domains is necessary and of immense importance. World Intellectual Property Organization (WIPO) addressed the respective issue via two treaties, i.e.,

1. World Intellectual Property Organization Copyright Treaty of 1996
2. World Intellectual Property Organization Performances and Phonograms Treaty of 1996

These treaties are implemented in the European Union, USA, Canada, as well as other nation states.

An agreement between member countries of European Union (EU) in 2001 regarding cybercrime is considered to be the first international initiative on computer crime. It is referred to as the Council of Europe - Convention on Cybercrime 2001. It has been implemented in July 2004 and signed by 37 countries.

It is a great effort which aids in the advancement of international cooperation through legislation of conventional cybercrime. It provides the basic framework and common legislative grounds to member countries, instead of their national laws for cybercrime. It is indeed, a landmark to prosecute cyber criminals, who commit crime in one country, but have an adverse effect on other countries.

Cyber security has become a global issue which undoubtedly demand a global approach for prevention of real time borderless exchange of classified and non-classified data by cyber criminals which are mostly attained through hacking.

The United Nations Congress on Crime Prevention and Criminal Justice emphasized on member states to develop an organized and international response to the misuse of ICTs. UN developed some guidelines and principles for the states to elaborate the legislation process. While, the implementation of such legislation are state's responsibility.

The United Nation Resolution 55/56 and 56/121 are an attempt to fight against the illegitimate use of ICTs and elimination of safe haven by requesting member states to incorporate effective legislation for the removal of such safe havens from their territory. Resolutions 57/239 and 58/199 addresses the need of awareness, adopting a global security culture, as well as protection of ICTs infrastructure from criminals.

The Organisation for Economic Co-operation and Development is an intergovernmental economic organization with 36 member countries, established in 1961. OECD replaced it guidelines published in 1992 regarding security policies with the Guidelines for the Security of Information Systems and Network 2002.

It provides a framework to member countries that support them in establishing the security for their interconnected communications systems and networks, along with the adaptation of security culture among users.

SOLUTIONS AND RECOMMENDATIONS

1. A strong global cyber force is required who can counter cyber threats.
2. Proper cybercrime data should be maintained by respective countries and it should be shared to the possible extent.
3. Victims of cybercrime are large in number, there should be easy access of the victims where they can complain regarding e-offenses.
4. Private companies should develop the liaison with the government officials to maintain the swiftness of their internet approach.
5. The respective legal departments should be equipped with the latest investigating technologies.

FUTURE RESEARCH DIRECTIONS

The significant areas for conducting future research encompassing cybercrime via engaging qualitative, qualitative, or eclectic approach can be:

1. Cybercrime and freedom of speech.
2. Low conviction rates of cyber criminals.
3. Cyberterrorism and cyber violence.
4. Cyber security issues.

CONCLUSION

In the contemporary era, the internet is indeed a very compelling invention, as it influence almost everyone who uses it. Research studies encompassing cybercrime are nominal as compared to conventional crimes. People who are more dependent on technology, become easy targets of cybercrime across the globe.

Nations worldwide are facing the hazards of cybercrime, because of numerous causes, poor technology, lack of cooperation with international law enforcing agencies, and absence as well as incapacity of legislation to financial constraints. Thus, solutions to the problems posed must be addressed by international law, necessitating the adoption of adequate international legal instruments.

Comprehensive cyber laws in an international context are a dire need of time. Furthermore, cyber laws have been developed in almost every developing as well as developed country, but their implementation is comparatively weak.

KEY TERMS AND DEFINITIONS

Cyber Security: Security on the internet.

Cybercrime: The use of a computer to commit a crime.

Cybercrime Legislation: The process of making laws regulating cybercrime.

Cyberterrorism: The use of information and communication technology to cause grave disruption or pervasive fear.

Cyberworld: The world of inter-computer communication.

International Cooperation and Legal Response to Cybercrime in Pakistan

Tansif Ur Rehman

University of Karachi, Pakistan

INTRODUCTION

According to Internet World Stats (IWS), the total number of internet users in Pakistan during October 2018 were 44,608,065, which is 22.2% of the total population. More than 30 million of Pakistan's 212 million people use the internet via mobile devices (Bytes for All, 2017). The literacy rate of the country is quite low as compared to other countries, i.e., 58 percent (Economic Survey of Pakistan, 2017).

Research studies into cybercrime with regards to the Pakistani context are nominal, as the field is relatively new. Pakistani has a perfect ecosystem regarding cybercrime, as the internet is widely available. Laws regarding cybercrime exist in Pakistan, but are rarely enforced. The respective culprits usually go largely unpunished in Pakistan. Most common types of cybercrime in Pakistan are criminal access, e-fraud and e-forgery, misuse of devices and encryption, cyberstalking, pornography, malicious code, spamming, unauthorized interception, cyberterrorism, attempt and aiding or abetting.

This research focuses on the common patterns of cyber criminals and the required legislation and enforcement of existing laws along with the need of international cooperation to counter global cyber threat.

OBJECTIVES

1. To highlight the main aims of Electronic Transactions Ordinance, 2002.
2. To highlight the formation of National Response Centre for Cyber Crime.
3. To critically analyze the role of Prevention of Electronic Crimes Act, 2016.
4. To highlight the legislation in Pakistan for international cooperation regarding cybercrime.
5. To discuss the legal response to cybercrime in Pakistan.

BACKGROUND

A bill has to be passed by both Houses of Parliament, i.e. the National Assembly and the Senate. Upon a bill's passage through both Houses, it is presented to the President of Pakistan for assent and becomes an Act of Parliament upon receiving such assent. In National Assembly's absence, statutes are promulgated by the President. The President may, if satisfied that circumstances exist which render it necessary to take immediate action, make and promulgate an Ordinance (Sial & Iqbal, 2015).

The respective framework, i.e., Electronic Transactions' Ordinance, 2002 has provided Pakistan with an initial legal backing regarding e-information as well as communication. National Response Centre for Cyber Crime (NR3C) formed in 2007 is another initiative taken by the Government of Pakistan to trace cyber criminals and to counter the internet misuse.

DOI: 10.4018/978-1-5225-9715-5.ch029

While, the National Assembly of Pakistan has passed the draft of Prevention of Electronic Crimes Act, 2016 (PECA) on 13th April, 2016 after making various amendments to it. PECA was drafted as being part of the National Action Plan (NAP), which was developed in response to the December 2014 attack on Army Public School, Peshawar. This attack took life of 150 people (including 132 children) (Khan, 2018). NAP is a 20 points plan for countering terrorism as well as extremism. It was drafted by the National Counter Terrorism Authority and Ministry of Interior. It got approval from the Parliament on December 24, 2014 (Haider, 2014).

Anusha Rahman Khan - Minister of State for Information Technology and Telecommunication of Pakistan and member of the committee for development of 'Prevention of Electronic Crimes Act, 2016' (PECA) admitted in a summarized note that, Pakistan has no such laws before to deal comprehensively with cybercrime. She belongs to Pakistan Muslim League (Nawaz), which is a centre-right conservative party in Pakistan. She also admitted that, criminal justice legal framework is ill equipped as well as inadequate and to resolve the respective threats of the cyber age.

Although, the PECA has been approved and came into system, but there is huge criticism from the opposition and the IT industry. Critics believe it to be harsh, with punishments not fitting the respective crimes. Another problem is the bill's language, as it could be abused by the government as well as law enforcement agencies in Pakistan.

FOCUS OF THE ARTICLE

This article focuses on the role of Prevention of Electronic Crimes Act (2016), legislation in Pakistan for international cooperation regarding cybercrime, as well as the legal response to cybercrime in Pakistan. This research also cites almost all relevant laws relevant to cybercrime, which have been legislated by the governmental body and defines what is illegal in the Pakistani context. This will help to understand the computer-related crime advancement, and how to use it as defined within the premises of law in the Pakistani context.

ELECTRONIC TRANSACTIONS ORDINANCE, 2002

The implementation of Electronic Transactions Ordinance, 2002 (ETO) has placed Pakistan in those few countries who understood the importance of cybercrime legislation in early time and provided imperative guidelines and frameworks which enabled and encourage the IT industry to foster at higher standards and spread of e-commerce in Pakistan. The Electronic Transaction Ordinance is of high importance that is necessary in carrying out proper IT growth and considered as a turning point for the Information and Communication Technology development as well as growth in Pakistani context.

Ordinance's Main Aim

1. Enhanced electronic transactions.
2. Legal and safe trading platforms for sellers as well as buyers.
3. Economic upheaval.
4. Growth in e-commerce and projection of surgical items, sports goods, leather goods, as well as textile products in the international market.

5. Enhanced punishments for offenses involving sensitive electronic systems.
6. Cost reduction strategies for small and medium business enterprises via e-transactions.

Main Clauses Cover Enlisted Offenses

1. Unauthorized interception
2. Spamming
3. Malicious code
4. Misuse of devices
5. Electronic fraud
6. Data damage
7. Criminal access
8. Issue of false certificate
9. Cyber terrorism
10. Spoofing
11. Cyberstalking
12. Misuse of encryption
13. Electronic forgery
14. System damage
15. Criminal data access
16. Damage to information system
17. Attempt and aiding or abetting
18. Provision of false information
19. Waging cyber war

NATIONAL RESPONSE CENTRE FOR CYBER CRIME

National Response Centre for Cyber Crime (NR3C) formed in 2007 is another initiative taken by the Government of Pakistan to trace cyber criminals and to counter the internet misuse. Regarding the 'Certificate Authority (CA)', the Ministry of Information Technology and Telecommunication (MoITT) formed the Accreditation Council in accordance with the National IT Policy and Electronic Transactions Ordinance, 2002.

This voluntary licensing program aims at promoting high integrity licensed CAs that can be trusted. A Certificate Authority aiming to acquire a license will adhere to a more stringent licensing criteria, which includes:

1. Strict security procedures as well as controls
2. Personnel integrity
3. Financial soundness

PREVENTION OF ELECTRONIC CRIMES ACT, 2016

The National Assembly of Pakistan has passed the draft of Prevention of Electronic Crimes Act, 2016 (PECA) on 13th April, 2016. One of the principal reason for drafting the respective Act was to provide a legal framework for attack against computers. Section 3 to 8 of this Act set out enlisted provisions.

1. Unauthorized access to data or Information System (IS).
2. Unauthorized transmission or copying of data.
3. Interference with data or Information System (IS).
4. Unauthorized access to data or Critical Infrastructure Information System (CIIS).
5. Unauthorized transmission or copying of Critical Infrastructure Data (CID).
6. Interference with data or Critical Information System (CIS).

LEGISLATION IN PAKISTAN FOR INTERNATIONAL COOPERATION

Chapter 4, Article 42, of the Prevention of Electronic Crimes Act, 2016 in this context states that;

1. The Federal government may upon receipt of a request, through the designated agency under this Act, extend such cooperation to any foreign government, 24 x 7 network, any foreign agency or any international organization or agency for the purposes of investigations or proceedings concerning offenses related to information systems, electronic communication or data or for the collection of evidence in electronic form relating to an offense or obtaining expeditious preservation and disclosure of data by means of an information system or real-time collection of data associated with specified communications or interception of data under this Act.
2. The Federal Government may forward to a foreign government, 24x7 network, any foreign agency or any international agency or organization any information obtained from its own investigations if it considers that the disclosure of such information might assist the other government, agency or organization etc., as the case be, in initiating or carrying out investigations or proceedings concerning any offense under this Act.
3. The Federal Government shall require the foreign government, 24 x 7 network any foreign agency or any international organization or agency to keep the information provided confidential and use it strictly for the purposes it is provided.
4. The Federal Government may, through the designated agency, send and answer requests for mutual assistance the execution of such requests or their transmission to the authorities competent for their execution.
5. The Federal Government may refuse to accede to any request made by a foreign government 24 x 7 network any foreign agency or any international organization or agency, if
 - a. It is of the opinion that the request, if granted, would prejudice sovereignty, security, public order or other essential public interest of Pakistan;
 - b. The offense is regarded by the Federal Government as being of a political nature
 - c. There are substantial grounds for believing that the request for assistance has been made for the purpose of prosecuting a person on account of that persons race, sex, religion, nationality, ethnic origin or political opinions or that that person's position may be prejudiced for any of those reasons;

- d. The request relates to an offense the prosecution of which in the requesting State may be incompatible with the laws of Pakistan;
 - e. The assistance requested requires the Federal Government to carry out compulsory measures that may be inconsistent with the laws or practices of Pakistan had the offense been the subject of investigation or prosecution under its own jurisdiction; or
 - f. The request concerns an offense which may prejudice an ongoing investigation or trial or rights of its citizens guaranteed under the Constitution.
6. Where the Federal Government decides to provide the requested cooperation, the relevant requirements and safeguards provided under this Act and rules framed thereunder shall be followed.
7. The designated agency shall maintain a register of requests received from any foreign government,²⁴ x 7 network, any foreign agency or any international organization or agency under this act and action taken thereon.

LEGAL RESPONSE TO CYBERCRIME IN PAKISTAN

Legal Response to Cyberterrorism in Pakistan

Regarding cyberterrorism Prevention of Electronic Crimes Act, 2016, article 10 and 12 of chapter two states;

“Whoever commits or threatens to commit any of the offenses under sections 6, 7, 8 or 9, where the commission or threat is with the intent to;

- a. Coerce, intimidate. create a sense of fear, panic or insecurity in the Government or the public or a section of the public or community or sect or create a sense of[lear or insecurity in society: or
- b. advance inter-faith, sectarian or ethnic hatred; or advance the objectives of organizations or individuals or groups proscribed under the law, shall be punished with imprisonment of either description for a term which may extend for fourteen years or with fine which may extend to fifty million rupees or with both.
- c. Recruitment, funding and planning of terrorism. Whoever prepares or disseminates information, through any information system or device, that invites or motivates to fund, or recruits people for terrorism or plan for terrorism shall be punished with imprisonment for a term which may extend to seven years or with fine or with both”.

Legal Response to Fraud in Pakistan

Regarding Cyber Fraud (PECA) in article 14, 23, 25, and 26 of chapter two (2) states:

Article 14 (Electronic Fraud):

Whoever with the internet for wrongful gain interferes with or uses any information system, device or data or induces any person to enter into a relationship or deceives any person, which act or omission is likely to cause damage or harm to that person or any other person shall be punished with imprisonment for a term which may extend to two years or with fine which may extend to ten million rupees or with both.

Article 23 (Malicious Code):

Whoever willfully and without authorization writes, offers, makes available, distributes or transmits malicious code through an information system or device, with intent to cause harm to any information system or data resulting in the corruption, destruction alteration, suppression, then or loss of the information system or data shall be punished with imprisonment for a term which may extend to two years or with fine which may extend to one million rupees or with both.

Article 25 (Spamming):

1. A person commits the offense of spamming, who with intent transmits harmful, fraudulent, misleading, illegal or unsolicited information to any person without permission of the recipient or who causes any information system to show any such information for wrongful gain.
2. A person including an institution or an organization engaged in direct mailing shall provide the option to the recipient of direct marketing to unsubscribe from such marketing.
3. Whoever commits the offense of spamming as described in sub-section (1) by transmitting harmful, fraudulent, misleading or illegal information, shall be furnished with imprisonment for a term which may extend to three months or with fine of rupees fifty thousand which may extend up to rupees five million or with both.
4. Whoever commits the offense of spamming as described in sub-section by transmitting unsolicited information, or engages in direct marketing in violation of sub-section for the first time, shall be punished with fine not exceeding fifty thousand rupees, and for every subsequent violation shall be punished with fine not less than fifty thousand rupees that may extend up to one million rupees.

Article 26 (Spoofing):

Whoever with dishonest intention establishes a website or sends any information with a counterfeit source intended to be believed by the recipient or visitor of the website, to be an authentic source commits spoofing

Legal Response to Hate Crime in Pakistan

Regarding Hate crime (PECA) in article 11 of chapter two (2) states;

Whoever prepares or disseminates information, through any information system or device, that advances or is likely to advance interfaith, sectarian or racial hatred, shall be punished with imprisonment for a term which may extend to seven years or with fine or with both.

Legal Response to Sexualized Content in Pakistan

Regarding sexualized content (PECA) in article 21 and 23 of chapter two states:

1. Whoever intentionally and publicly exhibits or displays or transmits any information which,
 - a. Superimposes a photograph of the face of a natural person over any sexually explicit image or video, or

- b. Includes a photograph or a video of a natural person in sexually explicit conduct; or
 - c. Intimidates a natural person with any sexual act, or any sexually explicit image or video of a natural person;
 - d. Cultivate, entices or induces a natural person to engage in a sexually explicit act,
 - e. Through an information system to harm a natural person or his reputation, or to take revenge, or to create hatred or to blackmail, shall be punished with imprisonment for a term which may extend to five years or with fine which may extend to five million rupees or with both.
2. Whoever commits an offense under sub-section (1) with respect to a minor shall be punished with imprisonment for a term which may extend to seven years and with fine which may extend to five million rupees: Provided that in case of a person who has been previously convicted of an offense under sub-section (1) with respect to a minor shall be punished with imprisonment for a term of ten years and with fine.
3. Any aggrieved person or his guardian, where such person is a minor, may apply to the Authority for removal, destruction of or blocking access to such information referred to in sub-section (1) and the Authority, on receipt of such application, shall forthwith pass such orders as deemed reasonable in the circumstances including an order for removal, destruction, preventing transmission of or blocking access to such information and the Authority may also direct any of its licensees to secure such information including traffic data.

Legal Response to Child Pornography in Pakistan

1. Whoever intentionally produces, offers or makes available, distributes or transmits through an information system or procures for himself or for another person or without lawful justification possesses material in the information system that visually depicts
- a. A minor engaged in sexually explicit conduct
 - b. A person appearing to be a minor engaged in sexually explicit conduct or
 - c. Realistic images representing a minor engaged in sexually explicit conduct or
 - d. Discloses the identity of the minor,

shall be punished with imprisonment for a term which may extend to seven years, or with fine which may extend to five million rupees or with both”.

2. Any aggrieved person or his guardian, where such person is a minor, may apply to the Authority for removal, destruction of or blocking access to such information referred to in sub-section (1) and the Authority, on receipt of such application, shall forthwith pass such orders as deemed reasonable in the circumstances, including an order for removal, destruction, preventing transmission of or blocking access to such information and the Authority may also direct any of its licensees to secure such information including traffic data.

Legal Response to Cyberstalking in Pakistan

Regarding Cyberstalking (PECA) in article 24 of chapter two (2) states that

1. A person commits the offense of cyber stalking who, with the intent to coerce or intimidate or harass any person, uses information system, information system network, the internet, website, electronic mail or any other similar means of communication to
 - a. Follow a person or contacts or attempts to contact such person to foster personal information repeatedly despite a clear indication of disinterest by such person
 - b. Monitor the use by a person of the internet, electronic mail, text message or; my other form of electronic communication;
 - c. Watch or spy upon a person in a manner that results in fear of violence or serious alarm or distress, in the mind of such person; or
 - d. Take a photograph or make a video of any person and displays or distributes it without his consent in a manner that harms a person.
2. Whoever commits the offense specified in sub-section (1) shall be punished with imprisonment for a term which may extend to three years or with fine which may extend to one million rupees or with both: Provided that victim of the cyber stalking under sub-section
 - a. Is a minor the punishment may extend to five years or with fine which may extend to ten million rupees or with both.
3. Any aggrieved person or his guardian, where such person is a minor, may apply to the Authority for removal, destruction of or blocking access to such information referred to in sub-section (1) and the Authority, on receipt of such application, shall forthwith pass such orders as deemed reasonable in the circumstances including an order for removal, destruction, preventing transmission of or blocking access to such information and the Authority may also direct any of its licensees to secure such information including traffic data.

CRITICISM OF PECA

Prevention of Electronic Crimes Act, 2016 is also facing harsh criticism from different political groups, religious groups, INGOs, NGOs, as well as CBOs. According to them, punishment lacks the relevancy to crime, and there are also many ambiguities in the respective act which may cause suffering to users by law enforcers in Pakistan (Jahangir, 2018; Khan, 2016).

ICTs organizations and cybercrime specialist were not taken on-board during the preparation of the act. It is also said that restrictions have been imposed on freedom of expression and access to available information on cyberworld. As cybercrime has a relation to the physical world, many articles in this act are overlapping with previously existing laws. Critics feel that this act can be misused against journalists as well as whistle blowers.

The surveillance criteria does not match the existing act of Fair Trial 2013. How law enforcing agencies will make its implementation possible, while the criminal trial procedure is unclear.

Although critics are claiming that cyberterrorism is not the subject of the bill, therefore terrorism clauses should be removed. While, the world perceives cyberterrorism as the most dangerous threat from intruders. According to a leading United States' newspaper report, i.e., New York Times by David E. Sanger and William Broad (2018), the USA government is even considering the use of nuclear weapon in the fight against cybercrime.

It is unclear how Pakistani authorities will block or remove online material, and which material will be considered illicit, will law enforcers need court orders to remove online material? Critics are having

difficulties in differentiating cyberterrorism and cyberwarfare, that whether it is a category of cybercrime or has some other definite form in the context of Pakistan.

SOLUTIONS AND RECOMMENDATIONS

1. General public awareness programs should be initiated with regards to cybercrime in Pakistan.
2. During the process of legislation regarding cybercrime in Pakistan, expert opinion should be included, like criminologists, psychologists, sociologists, IT professionals, etc.
3. Pakistan should maintain proper cybercrime data.
4. Victims of cybercrime are large in number, there should be easy access of the victims where they can complain regarding e-offenses.
5. Private companies should develop a strong liaison with the Government of Pakistan regarding the swiftness of their internet approach.
6. Pakistani legal department should be equipped with the latest investigating technologies.
7. Pakistani scholars should discuss cybercrime issue on different forums, specially in print as well as electronic media.
8. To effectively deal with cases of cybercrime, the respective judiciary must be given proper training.

FUTURE RESEARCH DIRECTIONS

The significant areas for conducting future research encompassing cybercrime via engaging qualitative, qualitative, or eclectic approach can be:

1. Cybercrime and freedom of speech in Pakistan.
2. Low conviction rates of cyber criminals in Pakistan.
3. Cyberterrorism and cyber violence in Pakistan.
4. Cyber security issues in Pakistan.

CONCLUSION

For developing countries, like Pakistan to trade with the developed ones, they must ensure that their national legislation ensures the same level of protection granted by other countries regarding storage and processing of personal data. This is imperative if these countries want to trade with European Union countries, which possess a very strong data protection laws.

The Federal Investigation Agency (FIA) of Pakistan was allowed by the Ministry of Interior to establish 15 cybercrime reporting centres across the country in October 2018 (Azeem, 2018). According to the FIA Cybercrime Director Captain Mohammad Shoaib (June 2018) statement, in the last three years, cybercrime has increased sharply in Pakistan. He further shared with the Standing Committee - Senate of Pakistan that, the Federal Investigation Agency has 10 experts only to investigate cybercrime (Qarar, 2018).

KEY TERMS AND DEFINITIONS

Cyber Security: Security on the internet.

Cybercrime: The use of a computer to commit a crime.

Cybercrime Legislation: The process of making laws regulating cybercrime.

Cyberstalking: The use of information and communication technology to frighten or harass an individual or group.

Cyberterrorism: The use of information and communication technology to cause grave disruption or pervasive fear.

Cybersecurity Laws in Malaysia

INTRODUCTION

The progression of information and communication technologies (ICT) use have been matched by the rise in corruption and abuse of technology for criminal activities. Regarding computer crimes in Malaysia, the Malaysia Computer Emergency Response Team (MyCERT) reported 3,743 incidents from January to May of 2019. Fraud incidents at 2,563 ranking the highest reported incidents for 2019 and “intrusion” incidents at 432 ranking the second highest incidents. In 2018, the total incidents reported to MyCERT was 10,699, of which “fraud” again had the highest reported incidents (5,123) and the second highest “intrusion attempt” at (1,805) of the total incidents. Between 2014-2017, the total number of incidents (Cyber harassment, Content related, Denial of Service, Fraud, Intrusion, Intrusion Attempt, Malicious Codes, Spam, Vulnerabilities report) gradually decreased from 11,918 incidents in 2014 to 7,962 incidents, a decrease of 3,956 or 33.2% in 2017. The statistics show that Malaysia’s cybercrime incidents have increased again in 2018 despite the country’s attempts at mitigating cybercrime. Cybercrimes are borderless and the threat of a cyberattack or cybercrime is there. To combat such criminal activities today in Malaysia, cyber laws have existed since 1997 to include: Computer Crimes Act 1997, Digital Signature Act 1997, Communications and Multimedia Act 1998, Payment Systems Act 2003, Electronic Commerce Act 2006, Personal Data Protection Act 2010 and Malaysian Penal Code to combat criminal activities such as fraud. While the cyber laws and law enforcement agencies exist in Malaysia, cybercrimes still pose a daunting challenge. The objective of this chapter is to analyse the existing cyber security legislations in Malaysia to combat cybercrimes in the country.

DOI: 10.4018/978-1-5225-9715-5.ch030

BACKGROUND

In 1991, Malaysia Vision 2020 by Prime Minister Mahathir Mohamad was presented during the Sixth Malaysia Plan. Malaysia Vision 2020 was the prime minister's vision for Malaysia to become a developed nation by 2020, which included his thoughts on how the nation can achieve this goal by meeting nine specific objectives. These nine objectives as he pointed out in his vision were to establish the following:

1. United Malaysian nation
2. Secure and developed Malaysian Society
3. Mature democratic society
4. Fully moral and ethical society
5. Matured liberal and tolerant society
6. Scientific and progressive society, a society that is innovative and forward looking, one that is not only a consumer of technology but also a contributor to the scientific and technological civilisation of the future
7. Fully caring society and caring culture
8. Economically just society
9. Prosperous society, with an economy that is fully competitive, dynamic, robust and resilient.

Malaysia Vision 2020 catapulted initiatives to support Prime Minister Mahathir's agenda, one of these listed as objective six: to establish a scientific and progressive society. Thus, Multimedia Super Corridor (MSC) Malaysia was launched in 1996 and the first cyber laws of Malaysia were introduced: Computer Crimes Act 1997, Telemedicine Act 1997, Copyright (Amendment) Act 1997, and Digital Signature Act 1997. Communication and Multimedia Act 1998 followed one year later and then: Payment Systems Act 2003, Electronic Commerce Act 2006, and Personal Data Protection Act 2010. The foundation established by these early cyber laws were to prepare the nation to embark on innovations and protect Malaysians using new innovations. The laws most relevant to current cybercrimes experienced in Malaysia will be discussed further in the subsequent section.

Malaysia, a country with a population of 32.7 million located in Southeast Asia was ranked third overall in the world behind Singapore and United States in the 2017 Global Cyber security Index (GCI), (International Telecommunications Union, 2017, July 6) and currently 8th place in the 2018 GCI global ranking. GCI is a survey that measures the commitment of the International Telecommunications Union (ITU) Member States to cyber security in order to raise awareness, which is driven by five pillars (legal, organisational, capacity building, and cooperation). However, as mentioned above, while the incidents reported by MyCERT have decreased from 2014-2017, the reported incidents have increased since then by 2,737 incidents in 2018. Table 1 below shows the top five reported incident categories (Fraud, Intrusion, Intrusion Attempt, Spam, Malicious Code) by MyCERT from 2010-2018, with the exception of "Cyber Harassment" making it to the top 5 incidents in 2018 overtaking Spam incidents. 2011 was the year Malaysia had the highest overall reported incidents in fraud (5,328) and spam (3,715). Intrusion (4,326) was the highest in 2012 and intrusion attempt (1,805) was highest in 2018, while malicious code (1,751) ranked highest in 2013. The trend overall shows that Fraud incidents across 2010-2018 consistently ranked the highest in incident reports with current 2018 statistics showing an increase in cyber harassment, intrusion attempt and malicious code incidents.

Table 1. Top five reported incidents MyCERT 2010-2018

	2010	2011	2012	2013	2014	2015	2016	2017	2018
Fraud	2212	5328	4001	4485	4477	3257	3921	3821	5123
Intrusion	2160	3699	4326	2770	1125	1714	2476	2011	1160

Table 2. MyCERT total reported incidents 2010-2018

	2010	2011	2012	2013	2014	2015	2016	2017	2018
Total	8090	15218	9986	10636	11918	9915	8334	7962	10699

Source: MyCERT Incident Statistics 2018

According to MyCERT in Table 2 above, in 2018, the total reported incidents amounted to 10,699. This increase since 2017 shows that although Malaysia is ranked third overall according to the GCI, the country is still vulnerable to cyberattacks and must stay vigilant in order to fight the ongoing battle against cyber criminals. Possibly because while both companies and educational institutions allow their employees and students to bring their own devices i.e. laptops, mobile phones to the workplace and educational environment, can ensure availability to knowledge it also may increase the chance of a cyber-attack on the institutional network (Ismail, Singh, Mustafa, Keikhosrokiani, & Zulkefli, 2017). The risk of having such policy in the workplace or educational institution, requires a policy or best practices for users of the network to prevent a cyberattack event to ensure a safer experience (Ismail et.al, 2017). That said, even with cyber laws in place, cybercrimes in Malaysia amounted to losses in 67.6 million Malaysian ringgit or USD 16.3 million as of April 2019. Previously, in 2018, cybercrime was responsible for almost 300 million Malaysian ringgit in losses or USD 72.3 million. The losses were due to mainly fraud cases i.e. telephone scams, e-commerce scams, e-financial fraud, credit card fraud etc. Despite reports of the Malaysian government's initiatives to bring awareness of cybercrimes to the public, Malaysian citizens continue to experience increasing cybercrimes as shown in Table 1 and Table 2 above. The next section includes the pertinent Malaysia Cyber laws and current cybercrimes in Malaysia.

MALAYSIA CYBER LAWS

The Malaysia cyber laws were established since the inception of MSC Malaysia. In the subsequent paragraphs, the main points of each cyber law, National policy and Penal Code most relevant to current cybercrimes in Malaysia will be highlighted and discussed (Computer Crimes Act 1997, Communications and Multimedia Act 1998, Copyright (Amendment) Act 1997, Personal Data Protection Act 2010, National Cyber security Policy and Penal Code).

Computer Crimes Act 1997

The Computer Crimes Act 1997 is a law “to provide for offences relating to the misuse of computers.” The Act was effective as of the June 1, 2000 and covers “unauthorised access to computer material, unauthorised access with intent to commit other offences and unauthorised modification of computer contents.”

The Computer Crimes Act 1997 was written to protect citizens from crimes concerning the misuse of computers. Computer Crimes Act section 9(1) states that “offences apply regardless of the nationality or citizenship, outside or within Malaysia.” This is a clear statement in the Act to protect Malaysians due to the borderless nature of the Internet. Thus, the Act applies to offenders outside Malaysia as well.

The offences are listed below along with their respective penalties upon conviction under the Malaysian Computer Crimes Act 1997:

1. **Section 3:** Unauthorized access to computer material
 - a. Section 3(3) fine not exceeding RM50,000 (approximately USD12,000) or imprisonment for a term not exceeding five years or both
2. **Section 4:** Unauthorized access with intent to commit or facilitate commission of further offence
 - b. Section 4(3) fine not exceeding RM150,000 (approximately USD36,000) or to imprisonment for a term not exceeding ten years or to both
3. **Section 5:** Unauthorized modification of the contents of any computer
 - c. Section 5(4) fine not exceeding RM100,000 (approximately USD24,000) or to imprisonment for a term not exceeding seven years or to both; or be liable to a fine not exceeding RM150,000 or to imprisonment for a term not exceeding ten years or both, if the act is done with the intention of causing injury as defined in the Penal Code
4. **Section 6:** Wrongful communication
 - d. Section 6(2) fine not exceeding RM25,000 (approximately USD6,000) or to imprisonment for a term not exceeding three years or to both
5. **Section 7:** Abetments and attempts punishable as offences
 - e. s.7(2) liable to the punishment provided for the offence: provided that any term of imprisonment imposed shall not exceed one-half of the maximum term provided for the offence

The cases below are examples of most recent computer crime cases in Malaysia.

In 2016, *Basheer Ahmad Maula Sahul Hameed v. Public Prosecutor*, the accused persons were convicted under section 4(1) of the Computer Crimes Act 1997 for wrongfully using a debit card belonging to an airplane accident victim to withdraw cash from an ATM machine and for transferring money from several other victims' online banking accounts without authorisation.

In 2016, *Rose Hanida Binti Long v. Pendakwa Raya*, the accused was charged under the Computer Crimes Act 1997 section 4 and Penal Code section 420 for using her superior's account and password without his knowledge. The High Court Judge sentenced her to 6 years imprisonment and fine of 260,000 Malaysian ringgit or 62,700 USD in default of 15 months jail due to the seriousness of the offence.

In 2016, *Public Prosecutor v. Roslan and Anor*, the accused who was an IT Systems Analyst for the Malaysian Hajj Pilgrims Fund Board, was convicted under Computer Crimes Act 1997 section 5(1) for modifying customer records in the organisation's database without authorisation.

In 2016, *Public Prosecutor v. Vishnu Devarajan*, the accused was charged under section 5 of the Computer Crimes Act 1997 for committing the following without authorisation: downloading and

launching software; running and stopping certain processes on servers; and running certain programs on the database server of a broadcast centre.

However, all charges were dropped due to technical and procedural errors in the prosecution of the case.

In 2017, *Kangaie Agilan Jammany v. Public Prosecutor*, the accused, an Air Asia employee was charged under section 5 of the Computer Crimes Act 1997 for making modification of the contents of Air Asia's flight booking system without authorisation. The accused had allegedly used the function "move flight function" to make unauthorized modifications to passengers; flight schedules. The function allows authorised staff to make changes so that no charges are made to customers. In this case, the accused misused another staff's agent code to help his family members and friends to get discounted airline tickets. Due to this action by the accused, Air Asia alleged that the company lost about RM229,100 or USD 55,300. Both the Sessions Court and High Court found the accused guilty.

In 2018, *Public Prosecutor v. Datuk Gee Siew Yee*, the accused was charged with accessing a computer without authorization under section 3(1) of the Computer Crimes Act 1997. She was accused of unauthorised access to a computer that belonged to IT manager Brian Periera, with intent to access three files pertaining to Kelab Taman Perdana Diraja (Royal Lake Club) meetings.

As seen in the above cases, the charges were under sections 3,4, and 5 and as mentioned in the previous section, statistics on intrusion attempts have increased in 2018. Due to this, the fines and penalties may need to be reviewed. Awareness training for both private and public sectors and beginning at the academic level could also help as preventive measures.

Communications and Multimedia Act 1998

The Communications and Multimedia Act (CMA) 1998 is the law to "regulate the converging communications and multimedia industries, and for incidental matters."

The Act came into effect on April 1, 1999, and "provides a regulatory framework to cater for the convergence of the telecommunications, broadcasting and computing industries." The Act encompasses communications over the electronic media and regulates the activities by "network facilities and service providers, application/content application services providers" (Manap, 2015).

As stipulated, the Act was established in 1 November 1998 and since then, cases have been taken to the court under section 211 "Prohibition on provision of offensive content" and section 233 "Improper use of network facilities or network systems" of the CMA 1998. In January 2016 to July 2017, a total of 227 cases involving misuse of social media and websites were investigated according to Deputy Communications and Multimedia Minister Datuk Jailani Johari. "19 cases were compounded and eight prosecuted and convicted" Jailani said.

On February 20, 2018, Fahmi Reza was imprisoned for one month and fined 30,000 Malaysian ringgit or USD 7,238 for posting an edited version of then Prime Minister Najib Razak on social media. Fahmi was charged under Section 233(1)(a) of CMA 1998 and punishable under Section 233(3) for posting the image of the Prime Minister as a clown. Under the Act, Fahmi was guilty of transmitting content that is "obscene, indecent, false, menacing or offensive in character with intent to annoy, abuse, threaten or harass another person".

In *Nik Adib Bin Nik Mat v. Public Prosecutor*, the accused was charged under section 233(1)(a) of the CMA for sending indecent and false photos of cabinet leaders titled "Pesta Bogel" on Facebook. He was also charged under section. 5(1)(a) of the Film Censorship Act 2002 for possession of 883 pieces of pornographic videos in his laptop. The Session Court sentenced him to the maximum sentence of one year imprisonment for the first offence and another year imprisonment for the second offence. On appeal,

the High Court sentenced the accused to one week imprisonment and a fine of 3,000 Malaysian ringgit or approximately USD 724 in default 3 months imprisonment for the first charge and for the second charge, a fine of 10,000 Malaysian ringgit or approximately USD 2,400 in default 1.5 years imprisonment.

CMA has recently been discussed by the Malaysian government. In 2018, the Communications and Multimedia Minister, Gobind Singh Deo said that the new government Pakatan Harapan's (PH) manifesto called to repeal and amend the legislation to remove elements that are draconian. In the past, section 233 was primarily used to charge opposition members against the government. The minister mentioned that the government will look into section 233 to tighten the legislation to ensure fairness in regulating multimedia. This is a good way forward for Malaysia in revisiting the CMA and amending/repealing parts of the legislation to make it a more effective.

Copyright (Amendment) Act 1997

The Copyright (Amendment) Act 1997 is the law “relating to copyright and for other matters connected therewith.”

The Copyright (Amendment) Act 1997 amended the Copyright Act 1987 and came into force on April 1, 1999 to “make unauthorised transmission of copyright works over the Internet an infringement of copyright”. Copyright (Amendment) Act 1997 s. 7 states that the following are eligible for copyright: “literary works, musical works, artistic works, film, sound recording and broad casts”. However, s. 7(3) of the Act states that the above works are not eligible for copyright unless:

1. Sufficient effort has been expended to make the work original in character; and
2. The work has been written down, recorded or otherwise reduced to material form.

Therefore, according to the Act, an idea be it of the eligible works described above, may not be copyrighted unless s.7(3)a and s.7(3)b are satisfied.

The Act specifically states that a qualified person is the author if the work:

Section 10(1) states that copyright shall subsist in every work eligible for copyright of which the author or in the case of a work of joint authorship, any of the authors is, at the time when the work is made, a qualified person.

Eligible work for copyright also applies to work created in Malaysia as described in section 10(2) whereby:

1. Being a literary, musical or artistic work or film or sound recording is first published in Malaysia;
2. Being a work of architecture is erected in Malaysia or being any other artistic work is incorporated in a building located in Malaysia;
3. Being a broadcast is transmitted from Malaysia.

Section 41 of the Copyright (Amendment) Act 1997 describes the offences, which include:

Any person who:

1. Makes for sale or hire any infringing copy;
2. Sells, lets for hire or by way of trade, exposes or offers for sale or hire any infringing copy;

3. Distributes infringing copies;
4. Possesses, otherwise than for his private and domestic use, any infringing copy;
5. By way of trade, exhibits in public any infringing copy;
6. Imports into Malaysia, otherwise than for his private and domestic use, an infringing copy;
7. Makes or has in his possession any contrivance used or intended to be used for the purposes of making infringing copies;
8. Circumvents or causes the circumvention of any effective technological measures referred to in subsection (3) of section 36;
9. Removes or alters any electronic rights management information without authority; or,
10. Distributes, imports for distribution for communicate to the public, without authority, works or copies of works in respect of which electronic rights management Information has been removed or altered without authority.

If any person is found guilty of any of the offences (a-j) described above, then he will be subject to according to the Act:

A fine not exceeding: ten thousand ringgit for each infringing copy, or to imprisonment or a term not exceeding five years or to both and for any subsequent offence, to a fine not exceeding twenty thousand ringgit for each infringing copy or to imprisonment for a term not exceeding ten years or to both.

However, for an offence under paragraph g:

A fine not exceeding twenty thousand ringgit for each contrivance in respect of which the offence was committed, or to imprisonment for a term not exceeding ten years or to both and for any subsequent offence to a fine not exceeding forty thousand ringgit for each contrivance in respect of which the offence was committed or to imprisonment for a term not exceeding twenty years or to both.

The following are examples of cases under the Copyright (Amendment) Act 1997:

In 2009, *Chuah Gim Seng & More Again v. SO*, the accused were found guilty and convicted for the sale of pirated copy films. The penalty imposed was RM2,000 (approximately USD480) for the sale of each copy and in default a four-month jail term for failure to pay each charge.

In 2011, *Public Prosecutor v. Haw Swee Po*, the accused was tried for possession and use (other than for private and domestic use) of 3,300 copies of seven films in DVD format. The court sentenced the accused to 14 months' imprisonment.

Copyright infringement cases as mentioned above still remain and are practiced frequently. The fines and penalties for this crime should be reviewed and increased. Moreover, awareness training on wrongful use of pirated films should be made more public and discouraged to prevent future copyright infringement cases.

Personal Data Protection Act 2010

The Personal Data Protection Act 2010 is the law to “regulate the processing of personal data in commercial transactions and to provide for matters connected therewith and incidental thereto.” The Act does not include the Federal and State governments according to section 3(1).

The Act is based on seven principles:

- General Principle
- Notice and Choice Principle
- Disclosure Principle
- Security Principle
- Retention Principle
- Data Integrity Principle
- Access Principle

According to Section 2(1), this Act applies to:

1. Any person who processes; and
2. Any person who has control over or authorizes the processing of, any personal data in respect of commercial transactions.

Section 2(2) describes the application and jurisdiction purposes whereby:

1. The person is established in Malaysia and the personal data is processed, whether or not in the context of that establishment, by that person or any other person employed or engaged by that establishment; or
2. *The person is not established in Malaysia, but uses equipment in Malaysia for processing the personal data otherwise than for the purposes of transit through Malaysia.*

Section 3(2) of the Act states that “any personal data processed outside Malaysia shall not apply unless that personal data is intended to be further processed in Malaysia.”

Furthermore, s. 6(3) of the Act states that personal data shall not be processed unless—

1. The personal data is processed for a lawful purpose directly related to an activity of the data user;
2. The processing of the personal data is necessary for or directly related to that purpose; and
3. *The personal data is adequate but not excessive in relation to that purpose.*

The first case to be charged under the Personal Data Protection Act 2010 occurred on 3 May 2017. Khas Cergas Sdn Bhd, which operates Victoria International College, was charged in the Sessions Court for processing personal data of former employees of the college without a valid certificate of registration issued by the Personal Data Protection Department (PDPA), in violation of section 16(1) of the PDPA. Section 16(1) requires certain classes of data users to be registered and to be issued with a valid certificate of registration by the PDPA.

This legislation is relevant only to institutions, organizations handling personal data in commercial transactions. Although training on PDPA and public awareness is made of the law in Malaysia, the case of Victoria International College still occurred. The law may need to be reviewed if not for its current fines and penalties, but for its definition of personal data. In this digital age, use of personal data in the internet for identification purposes is common place and PDPA has yet to include “biometrics” or a definition referring to such traits in the legislation.

Malaysian Penal Code

The Malaysian Penal code is the law relating to criminal offences. It is with this law that criminal offences not covered in the previous cyber laws discussed can convict offenders for crimes such as sale / distribution of pornography, ransomware, and fraud. The below sections from Penal Code describes the applicable sections:

Section 292 is the selling, distribution, or public exhibition of obscene materials.

For this offence if convicted, the offender shall be imprisoned for a term “which may extend to three years or with fine or with both.”

Section 293 is the selling, distribution of obscene materials to minors or a “person under the age of twenty” years old or offers or attempts to do so.

For this offence if convicted, the offender shall be imprisoned for a term, which may “extend to five years or with a fine or with both”

Section 383 states that “whoever intentionally puts any person in fear of any injury to that person or to any other, and thereby dishonestly induces the person so put in fear to deliver to any person any property or valuable security, or anything signed or sealed which may be converted into a valuable security, commits ‘extortion’.”

The punishment for extortion as stated in s. 384 “imprisonment for a term which may extend to ten years or with a fine or with whipping or with any two of such punishments.”

Section 416 states that “any person is said to ‘cheat by personation’, if he cheats by pretending to be some other person, or by knowingly substituting one person for another, or representing that he or any other person is a person other than he or such other person really is.” The offence of cheating by personation is punishable with imprisonment for a term which may extend to seven years and/or a fine.

Section 422 states that “whoever dishonestly or fraudulently prevents any debt or demand due to himself from being made available for his creditors shall be punished with imprisonment for a term which may extend to five years or with a fine or with both.”

Section 424 states that “whoever dishonestly or fraudulently conceals or removes any property of himself or any other person, or dishonestly or fraudulently assists in the concealment or removal thereof, or dishonestly releases any demand or claim to which he is entitled, shall be punished with imprisonment for a term which may extend to five years or with fine or with both.”

In 2016, *Public Prosecutor v. Charles Sugumar a/l M. Karunnanithi*, the accused tour driver was charged under section 424 of the Penal Code for dishonestly concealing money of a scam victim in his bank account. The victim had befriended a person by the name of Alfred Hammon from UK through Facebook. Alfred Hammon then made the victim transfer money to the accused’s bank account based on the pretence that he needed the money to cash a USD 3 million cheque and would return the money with interest. The Magistrate acquitted the accused and found that the accused was made a scapegoat by the customer who took advantage of his kindness.

The Malaysian Penal Code is the catch all legislation whereby for cases not covered by current Malaysian Cyber Laws, can be charged under. Although this may be a convenient at the moment, a more practical cyber law should remain in place to cover such charges. This law should also be periodically reviewed to keep up with current cybercrimes and relevant offences.

The cases and laws previously stated are not without national law enforcement agencies working with their international counterparts. In Malaysia, these agencies are the Royal Malaysian Police, National Cyber Security Agency, Cyber Security Malaysia, and Cyber999. Most recently, the National Cyber Security Agency of Malaysia was established as the leading agency to handle cyber security matters. The next section describes the agency and its functions.

National Cyber Security Agency

In February 2017, the National Cyber Security Agency (NACSA) for Malaysia's leading agency was established to handle cyber security matters, with the objectives of "securing and strengthening Malaysia's resilience in facing the threats of cyberattacks, by coordinating and consolidating the nation's best experts and resources in the field of cyber security" (National Cyber Security Agency, 2018)

National Cyber Security Policy

Vision Statement

Establishing a stable, safe and resilient cyber environment to meet the economic and social needs of Malaysia.

The Objectives of NACSA are:

- Address the risks to the Critical National Information Infrastructure (CNII)
- To ensure that critical infrastructure are protected to a level that commensurate with the risks
- To develop and establish a comprehensive program and a series of frameworks

The National Cyber Security Policy (NCSP) was developed based on a framework that comprises legislation and "regulatory, technology, public-private cooperation, institutional, and international aspects" (National Cyber Security Agency, 2018, December 6).

The ten sectors of the Critical National Information Infrastructure (CNII) that NCSP seeks to address the risks to are:

- National Defence and Security
- Banking and Finance
- Information and Communications
- Energy
- Transportation
- Water
- Health Services
- Government
- Emergency Services
- Food and Agriculture

NACSA's mission is to be committed towards the implementation of the national cyber security policy and management in an integrated and coordinated manner.

The NACSA's national cyber security policy comprises of Eight Policy Thrusts, which are:

Effective Governance

National cyber security initiatives are centralised with effective cooperation between public and private sectors and establish formal and foster informal information sharing

Legislative and Regulatory Framework

Enhance/review cyber laws to focus on the dynamic nature of cyber security threats and ensure legislations adhere to international treaties and conventions

Cyber Security Technology Framework

Ensure legislation is adheres to international laws, treaties and conventions and application of an evaluation/certification program for cyber security products and systems

Culture of security and Capacity Building

Develop and foster a national culture of security whereby cyber security awareness and education programs across CNII are standardised and such knowledge dissemination is effective at the national level

Research & Development Towards Self-Reliance

Strengthen the cyber security research community by “promoting the development and commercialization of intellectual properties, technologies and innovations through focused research and development” and foster the advancement of cyber security industry

Compliance and Enforcement

Develop standardised cyber security systems to strengthen the monitoring and enforcement of standards and create a standard of cyber security risk assessment framework

Cyber Security Emergency Readiness

- Strengthen the national computer emergency response teams (CERTs)
- Develop effective cyber security incident reporting mechanisms
- Encourage all elements of CNII to monitor cyber security events
- Develop a standard business continuity management framework
- Disseminate vulnerability advisories and threat warnings in a timely manner
- Encourage all elements of the CNII to perform periodic vulnerability assessment program

International Cooperation

- Encourage active participation in all relevant international cyber security bodies, panels and multi-national agencies
- Promote active participation in all relevant international cyber security by hosting an annual international cyber security conference

NACSA is still at its infancy and the country has yet to experience its effectiveness in handling cybersecurity matters and the effectiveness of its national strategy. The National Cyber Security Strategy will be issued by NACSA in mid-2019 according to Deputy Prime Minister Dr. Wan Azizah Wan Ismail. Of note, one of the main activities outlined in the National Security Council Directive is to implement a National Cyber Crisis Training Charter to test the effectiveness of procedures and familiarize CNII agencies with cyber incident handling.

SOLUTIONS AND RECOMMENDATIONS

The cyber security legislations of Malaysia require an on-going review as cybercrimes continue to grow and evolve as evidenced in the statistics and cases stated above. The Internet has both its positive and negative aspects. While it can be used for convenience and ease of use such as internet banking and e-commerce, the data a user provides to enter the website can be easily plucked by cyber criminals. In order for users to feel safer, they must practice safe cyber security housekeeping. This can be done by conducting knowledge sharing at the most basic level in schools to employee training during their first days of orientation in a new company. However, to ensure this practice is implemented, a national policy should include this standard training for every company and institution using computers. The National Cyber Security Policy has good aspects to its framework, however the policy is to be implemented only in mid-2019. The NACSA has only been established since 2017 and it is too early to say the effectiveness of the organisation. Imposing higher penalties on those convicted of cybercrimes may need to be implemented in the current legislation or future legislations to prevent criminals from doing the crime. Privacy under the PDPA 2010 is only applicable to companies handling personal data for commercial transactions and a definition under the Act is absent for biometric data. This aspect of PDPA should be reviewed in order to include all forms of personal data is protected under the PDPA.

FUTURE RESEARCH DIRECTIONS

Currently there is limited research in the area of cybersecurity in Malaysia. Future research in both qualitative and quantitative should be looked into and focus on law enforcement and effectiveness of current legislations.

CONCLUSION

Malaysia has great initiatives when it comes to their cyber security laws. The dedication of the country to provide a secure network environment is promising, with Malaysia establishing NACSA to lead in all cyber security aspects for the nation. Their national strategy is also said to be issued in mid-2019, which will further enable the government agency clear guidance on how to handle cyber security matters. However, with the advancement of technologies and the enthusiasm of the public to use technology, criminals will always find a way to leverage this for themselves. That is the reason why Malaysia must continue to stay vigilant and continue to review their legislations to protect their citizens from cyber criminals.

KEY TERMS AND DEFINITIONS

Cyber Security: The practice of defending computers and related systems mobile and fixed from attacks against hackers and cyber criminals.

Cyberattack: The act of hackers to disrupt or damage a computer network or system.

Cybercrimes: Criminal activities using the internet as a vehicle to commit the crime.

Fraud: The act of deceiving for personal monetary gain.

Intrusion: Wrongfully accessing a computer's system or network.

Malicious Code: Computer code often used by hackers to infiltrate a computer to cause damage and security vulnerabilities.

Spam: Messages sent via the internet often unimportant with the intent to advertise, induce malware and phishing programs.

Game Console Protection and Breaking It

2

Nezer Jacob Zaidenberg

College of Management, Israel

INTRODUCTION

This chapter presents a survey of the attacks and defenses on various video game consoles (hereby consoles). Consoles are complex embedded systems designed to run various video games. At the console release time, the console is comparable to a high-end gaming PC. In addition to gaming hardware, the console also features an operating system and libraries. Unlike general-purpose PCs that run just about any software, consoles are supposed to run only licensed code and games. Consoles also include complex Digital Rights Management (DRM) and copy protection mechanisms. The attacks presented here are usually geared toward running custom OSs, homebrew (unlicensed) software and pirated games on the console. Over the last 20 years, various groups discovered the attacks against different consoles. Most of the attacks were reported by in the annual CCC conference.

The survey focuses on recent generations of game consoles (6th, 7th and 8th generation) as these are more interesting from a console hacking perspective. Prior console attacks usually used custom hardware modifications (modchips). These attacks are not comparable to attacks on newer generations, and therefore, older consoles are beyond the scope of this chapter. Also, this chapter does not deal with mobile consoles. (Such as PSP, Vita, Nintendo DS etc.) Last, Many other devices that can be considered gaming devices, particularly mobile phones (iPhone/Android). Also, PC-gaming is very common. (and PC games also suffer from piracy). These devices are not considered game consoles and are beyond the scope of this chapter.

BACKGROUND

Consoles are a type of embedded system. Consoles offer processing capacities similar to a high-end PC.

However, unlike PCs, consoles hardware is geared entirely to run video games. At the time of release, consoles offer CPU, RAM, graphics capabilities and hard drive capacity comparable to a gaming PC. Furthermore, most consoles are cheaper than a comparable PC as the consoles' manufacturers subsidize consoles. The manufacturers sell the game consoles at a loss. Instead of profiting on console sales, the consoles' manufacturers profit when the users buy games.

Tools to attack the copy protection on consoles are as old as consoles themselves. However, the rising popularity of recent consoles has transferred the manufacturing modchips and tools to break the game console copyright protection is a flourishing business. As piracy is illegal, there are no official figures. However, the market size is significant. Console modchips cost roughly 50 USD apiece. Console sales often reach quantities of 40M to 100M units per model or even more in some cases. Most of these consoles are fitted with modchip at some point. These figures suggest that the modchip industry is a multibillion USD industry.

DOI: 10.4018/978-1-5225-9715-5.ch031

Legality

It is of course illegal to pirate games. However, it is legal for the end-user to modify equipment that he (the end-user) owns. (fair use) Such modification can be, for example, installing modchips or software, provided the goal is not running pirated software but running homebrew code or Linux. It is also legal for the end-user to create backups of CDs that the end-user owns. (Playing backup CD is identical from a technology standpoint to playing a copied CD)

Installing modchips creates a loophole because, in the United States and other jurisdictions, thanks to the Digital Millennium Copyright Act (DMCA) it is also illegal to create devices whose sole purpose is to break DRM (such as modchips) even if no piracy is committed. So, in the United States, selling modchips designed to copy games is also illegal. Other countries have different laws and, in some jurisdictions, selling modchips may be legal. This chapter focuses on the technology of attacks and defenses. The complicated international legal aspects of DMCA and game consoles are beyond the scope of this chapter.

Usually, modern console attacks no longer require modchips. However, it is worth noting that in 2011, Sony sued George Hotz (geohot) over DMCA violations regarding published PS3 attacks without using any modchip or hardware modifications.

The case was settled outside court, and Hotz committed not to hack another Sony product.

However, even software-only attacks (i.e. running code that the user has coded on an embedded device that the user owns) may result in legal action, in the USA.

Motivation

The obvious motivation beyond attacks on game consoles is piracy. Console games are expensive. Console games are even more expensive than PC games. The PC version of the same game is usually cheaper than the console version due to royalties collected by the console manufacturer to cover the subsidized cost of the console itself.

However, in addition to piracy, there are several other motivations behind attacking game consoles. The first of those is running other operating systems, usually Linux. As game consoles offer high-end (for the release time) hardware at subsidized costs using game consoles as regular computers and running Linux has appealed to hackers. Furthermore, according to DMCA, it is considered legal and fair use of the end-user equipment. The console manufacturer attempts to prevent running Linux as console games will not be purchased for Linux servers. Since the console itself is subsidized the manufacturer loses money if the end-user installs Linux on the console.

Another potential motivation is running homebrew software, i.e. software that the user coded (or open-source software the user compiled) on its own machine. This use case is also legal, according to DMCA. I.e. it is considered fair use.

There are two risks from the console manufacturer point of view with running homebrew code.

The first is unlicensed games. The console manufacturer is subsidizing the console sales but collecting royalties from any game sold. This is possible only because the manufacturer has complete control (using signatures) on what is allowed to run (whitelisted, signed) to run on the machine. Unlicensed games don't allow the manufacturer to collect royalties. Therefore, unlicensed games without paying royalties should not be allowed to execute on the machine.

The second problem with homebrew code is that it removes the manufacturer control over the entertainment system at the end-user's digital home. Console manufacturers frequently have additional goals in this field (enforcing standards, formats, operating systems to use etc.) Therefore, the console users

must use signed software controlled by the manufacturer. By allowing homebrew software, the console vendor loses control on the end-user digital home.

5th GENERATION AND OLDER CONSOLES

5th generation and older consoles did not have hard drives. Games were only distributed on proprietary cartridges or CDs. Older consoles (like Sony PlayStation etc.) were hacked almost entirely for software piracy purposes. These hacks were usually committed using modchips.

Modchips

Most consoles used off the shelf CPUs and other components. Using off the shelf components was inexpensive compared to custom components. However, off the shelf components did not provide proper copy protection mechanisms.

To provide copy protection, the older console had software running on top of an EPROM or BIOS chip that enforced copy protection. These chips were used only for copy protection and some simple functions (such as booting) and were not required for standard operations. “Modchips” were tiny electronic boards that were soldered to the game console board and circumvented the copy protection chip. The modchip often replaced another chip. The modchip then performed as the chip that it was supposed to replace. However, the modchip would not enforce copy protection. Opening the console box, cutting wires and replacing chips would void the console warranty. (but apparently, in many cases the end-user would not care).

Modern consoles are usually protected using software means (as opposed to hardware chip), and thus modchips are no longer used on modern consoles.

6th GENERATION CONSOLES

Xbox

Michael Steil offered a detailed summary of the Xbox weaknesses and design problems (Steil 2005). Microsoft wanted to release a console competing with Sony’s PlayStation 2 under a tight schedule. The tight schedule requirement led to a game console design that is closely related to a windows PC. (As Microsoft already had the source and capabilities for PC operating systems for games.)

The Xbox is running on top of almost a standard PC hardware for the time.

The Xbox includes an Intel Celeron III CPU, NVidia GeForce GPU, hard drive and memory (64MB of RAM).

This led hackers to the conclusion that “the Xbox is a PC”.

PCs, and thus the Xbox, have multiple legacy components. These components were later used to hack the Xbox and alter its behavior. The Xbox design had several critical mistakes (Steil’s paper provides a complete list) including

- Multiple design mistakes
- Failure to analyze attacker resources and attack vectors properly

- Implementation errors
- Failure to do sufficient audit possible due to release schedule requirements
- Failure to handle security incidents properly.

As a result of these errors, the Xbox hackers managed to hack the Xbox quite quickly.

Currently, the Xbox security is completely broken. Users can run pirated copies, homebrew software and Linux without even opening the Xbox.

Game Cube

The GameCube was released in 2001 by Nintendo. The game cube is a PowerPC G3 (PowerPC 756e codename Geko) running at 485 mhz with 40MB. The GameCube was comparable to PowerPC based macs released by Apple circa 2001. The GameCube provided attractive hardware for running homebrew applications much cheaper than comparable macs. The GameCube CPU is comparable to the Apple G3 CPU and includes MMU, vector processor features etc.

The GameCube included a DVD copy protection system in the DVD firmware. The DVD firmware refuses to boot from standard DVD. However, GameCube's DVD protection is faulty. The GameCube DVD had two major backdoors that could be used for attacks allowing modchips.

The DVDs of the GameCube were signed on manufacturing using some measurement of the recorded disc. This measurement could not be measured and replicated accurately. If a game is copied, then these measurements would be slightly different on the copy compared to the original these differences result in different signatures.

Thus, original games could be separated from copies. (SecureROM used similar protection for PC games)

For such protection to work the signature should have been using an asymmetric cypher, so the verification and signing key would be different. Different keys mean that the signing and verification keys are different.

If the signing and verification keys are identical, the manufacturer can sign the masters using a private key that is not revealed to the users. When using the same key for signing and verification (symmetric encryption), the user can calculate the new signature and sign self-created copies. Nintendo used symmetric cypher with the key stored that is stored on the DVD itself. Therefore, this protection was useless as the user could calculate and replace the signature.

Additionally, the GameCube DVD had a backdoor password attack that allowed modchips. The password was broadcasted to the DVD to state the disc is verified. The password was compared on the DVD using memcmp(3) function. Hackers revealed the password using a timing attack. Thus, the GameCube password was revealed.

Today the GameCube security is completely broken. Since users can sign their own copies, Users can run pirated copies, homebrew software and Linux without even opening the GameCube.

For further reading on GameCube protection, please refer to Domke et al. 2004.

Playstation 2

The PlayStation 2 (hereby PS2) is the bestselling game console of all times. There were over 150 million PS2 consoles sold worldwide.

The PS2 came with 299MHz MIPS based core (emotion engine), 32 MB of RAMBUS RAM and GPU clocked at 147 Mhz. The PS2 came without a hard drive by default but allowed for an optional hard drive.

Sony released Linux for PS2 on their own.

Most PS2 attacks were based on modchips that allowed pirated games to run. Sony has created several revisions to the console board and bios each time eliminating some of the modchips. The hacker community reacted with introducing new modchips to the revised board edition.

Brown 2003 offers a summary of the PS2 modchip efforts.

Today most PS2 that are still working are fitted with a modchip.

SEGA Dreamcast

Sega Dreamcast was the last console that Sega ever designed. It was released in 1998 and discontinued in March 2001 (before other “6th generation” consoles were even released). The Dreamcast had 200Mhz, 16MB of RAM. Like many old-consoles (such as the original PlayStation, Nintendo 64 etc.) the Sega Dreamcast was vulnerable to modchips attacks that allowed users to play pirated copies.

7TH GENERATION CONSOLES

Nintendo Wii

The Nintendo Wii was the first and most successful of the 7th generation consoles. It was released about a year ahead of its peers. (The PS3 and the 360) The Wii was very cheap compared to its competitors (The. 360 and PS3) and offered a unique playing experience using an innovative controller.

The Nintendo Wii is running on hardware similar to its predecessor, the GameCube.

The Wii's CPU is PowerPC G3 (same as the GameCube), but the Wii's CPU is clocked faster.

The Wii also has a similar memory structure in several memory banks. The Wii's extended memory bank offers 64 MB of memory in addition to 24MB main memory for a total 88 MB of memory. Thus, the Wii has 48MB more than the GameCube that had only 16MB of extended memory for a total of 40MB.

Unlike other consoles, the Wii was not sold at a significant loss, and thus hackers had less of motivation to purchase the Wii and use it as a Linux box.

The Wii software allows the execution of GameCube games in a “compatibility mode” that is identical to GameCube by simply downscaling the CPU and thus attacks that target the GameCube were also tested on the Wii. Most GameCube attacks worked on the Wii. Thus, Nintendo's Wii was partially broken on release as it was running the GameCube code and pirated GameCube copies (using faulty symmetric password mechanism) on compatibility mode.

Thus the Wii could run GameCube code and pirated copies but not homebrew code.

Hackers introduced the Twizzers attack to bypass the GameCube mode limitations.

Nintendo off course knew about the GameCube vulnerability at the time of the Wii release. However, since the GameCube was limited to only 16MB of RAM, Nintendo assumed that the rest of the memory is safe. Thus, Nintendo used the other 48MB for security purposes.

However, The PowerPC CPU on the Wii (like any other CPU) had an address line. In order to bypass the 16MB limitation of GameCube hackers used tweezers on the wii motherboards hackers to shorten the address lines. Thus hackers managed to move the 16MB that GameCube mode can access to other addresses physical address. Thus, hackers were eventually able to map and dump the entire Wii memory.

The memory that they dumped contained all the encryption keys.

The Wii keys that were now dumped allowed access to the ECC (elliptic curve cryptography) (Miller 1985) private key of the specific machine as well as the public key of Nintendo. It also contains AES and HMAC keys, The common key (for all Wii), the SD key and the root key. These keys were hardcoded in the Wii Operating System (IOS) and on a write once ROM.

Today, The Wii is still cracked for piracy and running homebrew and Linux.

The CCC console hacking lecture from 2006 describes breaking the Wii protection in GC mode.

The CCC console hacking lecture from 2008 by Marcan et al describes the Twiizers attack.

According to Bushing et al 2010 there were over 1M users in the Wii homebrew channel.

Xbox 360

Learning from Xbox mistakes, The Xbox 360 is very different from a PC. The Xbox 360 runs on a 3-core IBM PowerPC processor (3.2 Ghz) 512 MB of RAM. SATA hard drive (size varies according to exact model) and R600-class GPU

The Xbox 360 includes several security features such as

1. Security Hypervisor a “Type-1” hypervisor
2. Encrypted memory (So sniffing the buses as was done in the original Xbox will not be fruitful)
3. Data execution prevention i.e. W^X on memory pages
4. E-Fuses – E-Fuses are specific memory that exist on the CPU itself that can be “burned” after burning a fuse it cannot be “unburnt” it remains, physically burned on the CPU. The only way to “unburn” the E-Fuse is to replace the CPU.
5. CPU ID – The Xbox 360 processor had sufficient CPU fuses that could create a unique cpu id for each cpd by burning different fuses for each Xbox 360

The main attack against the Xbox 360 was “The King Kong” attack. This attack uses the fact that the 360 does not encrypts all the memory. Some memory must remain unencrypted for DMA etc.

A game can copy to memory using the pixel shader, part of the Video adapter. (not all games but the “King Kong” game, for example, does not check the pixel shader) thanks to a bug in the hypervisor the user can create a hyper call that calls jump to the copied memory and run unencrypted code. Thus homebrew code and Linux can be started.

Microsoft released a patch for XBOX which also blocks Linux. Furthermore, the patch burns some E-Fuse on the CPU. If the user ever upgrades the software, downgrade is impossible because of the software will check the E-Fuse and will not boot. Another attack that was discovered allowed modchips for the DVD drives that allow for pirated copies.

The XBOX 360 is an exception in the console scene.

It was broken for game piracy relatively early in its life cycle but has not been broken for running Linux and homebrew code in any consistent way since. (Except for the King Kong attack (Anonymous 2006) described above that was blocked relatively early.)

The XBOX 360 remains an exception in that it still does not run homebrew code and Linux.

This section is based mainly on Felix Dumke’s summary (Domke 2006) with some addition from Dumke’s previous lecture. (Steil 2005)

Playstation 3

2

The PlayStation 3 (hereby PS3) is unique as it remained secure platform for over 4 years. Well over any other platform. For a time breaking the PS3 was the “Holy Grail” hackers aspired to break. More than 87 Million PS3 were shipped.

The PS3 is running on a cell processor which is a Power PC processor.

The CPU is augmented by 8 vector processors. These vector processors are called SPEs.

These SPE are a single prevision float point unit for video processing, for games.

However, out of the 8 SPU only 6 are available for games.

One SPU is automatically disabled by design on all PS3s. This allows Sony to use defective CPUs (with one SPE damaged) reducing the CPU manufacturing costs. An additional SPU is always used for encryption and decryption of instructions leaving 6 SPU for general purpose usage. The SPU also have curtained memory that allows some memory to be shadowed from other processes.

The PS3 offered also 512MB of memory, a hard drive (of various sizes) and was heavily subsidized by Sony.

The Sony PS3 included “Cell OS level 1” a type-1 hypervisor and “Cell OS level 2” OS.

Initially Sony allowed for “other OS” a limited (but sufficient) Linux support. However, hackers used subverting attacks, i.e attacks by the guest OS on the host hypervisor, to dump the code of the hypervisor. Following the subverting attacks, Sony decided to drop support for “other OS” feature.

The PS3 security system also includes signing executables, signing storage, a security SPU.

The first attack on PS3 was attacking the secure storage. The secure storage encrypts everything with the same key. By copying stuff to the hard drive (like a movie) the hacker gets the encrypted version of everything that was copied. By moving stuff on the HD and reading it (for example, as a movie) we can get the decrypted version of everything on the HD. So any encrypted file can be deciphered by moving it and reading it using another application. Thus the PS3 secure storage was broken.

The hypervisor mapping bug which lead to exposure of the hypervisor code work was discovered by George “geohot” Hotz. The method is similar method to the Wii “Twiiizer” attack. It is relying on the fact that we have second level address translation, i.e. double page tables. one page table exist in hypervisor mode and another page table exists in Supervisor (OS) mode. geohot was able to bypass the memory protection by getting a pointer to cell-OS level-2 memory location while Cell-OS level-1 (the hyper visor) thinks that the same memory location is free. Since the hypervisor thinks that the memory is free at some point the hypervisor will map the hypervisor stuff to this free address. But as the cell-OS level-2 is still mapping this memory address it can read from this address and that led to the hypervisor code exposure. But even though the hackers now had access to the hypervisor code that has not led to any significant attacks for quite a while.

The first meaningful attack against was the PS3 jailbreak.

The PS3 jailbreak is a USB dongle that acts as a USB hub simulating multiple USB devices behind the hub. The dongle is exploiting a bug in the Cell OS in handling USB devices. The PS3 Jailbreak dongle allowed execution of random code on the PS3. At this point piracy was possible.

Through a series of other discoveries hackers have found serious implementation flaw in the way SONY signed binaries. SONY implemented the Elliptic Curve DSA (ECDSA) algorithm to sign their ELF's. ECDSA is a strong crypto infrastructure and a method that is still considered unbreakable. However, ECDSA relies on random numbers. (Or pseudo random numbers) Sony's faulty random number generator is always initialized with the same string and returns identical pseudo random numbers. Thus,

Sony ECDSA implementation is faulty. The faulty elliptic curve implementation in Sony PS3 was broken and the keys were leaked.

The private keys of Sony PS3 was leaked to the internet by Geohot on 2011. (Hotz 2011) These keys cannot be banned or blacklisted by Sony because all the old consoles still use these keys and must still work.

Today, after the private keys leaked to the internet, it is possible to run any software for the PS3. Running homebrew or pirated code and even Linux on the PS3 is possible. It does not require opening the PS3 or installing any USB dongles or modchips.

The PS3 has complete analysis of its security system available on (Bushing et al 2010) this section is based on this presentation.

8TH GENERATION CONSOLES

8th generation game consoles are the most recent generation. The common factor in many attacks against 8th generation consoles is attacking the web browser (webkit) using well known browser or webkit weaknesses.

Wii-U

The Wii-U was released in November 2012. The Wii-U offered a Tri-core PowerPC chipset, 2GB of RAM. The Wii-U has already been cracked (to play pirated games) about one month after its launch (Sven et al 2013).

Unlike the Wii the Wii-U has not been commercially successful (Takahashi 2013). Only 3.61M units were sold until the end of June 2013 which is relatively low compared to Wii or other 8th generation consoles. still the Wii-U offered better hardware then the Wii and an exotic hacking opportunity.

The Wii-U include hardware and software similar to the Wii (only faster).

The Wii-U security system had been a victim to its predecessor weakness of backward compatibility. Just like the Wii was hacked first in GameCube mode the Wii-U was hacked using the Wii compatibility mode.

The hacking of the Wii-U was possible due to the fact the Wii-U also includes Wii OS that run on real mode. Even though the Wii-U will only boot an encrypted and signed code all Wii weaknesses still existed in Wii-U. Therefore, the hackers could learn the new security measures using the old Wii methods.

The hackers were able to create a timing attack against the Wii by replacing the instructions in memory after their signature were verified and decoded. Using some custom hardware hackers were able to dump the Wii-U boot ROM. Shortly afterwards the hackers attacked the PPC HRESET bus and received the keys for Wii mode. (At this point the hackers had complete administrator access on the hardware, but were limited in Wii mode)

The secondary weakness of Wii-U was the webkit web browser. The Wii-U is using webkit that is an open-source software project with known bugs, vulnerabilities and attacks databases. Using Wii and webkit issues the hackers obtained the means for entering and leaving virtual Wii mode.

Nintendo discontinued the unsuccessful console on 2017 after releasing the switch and selling only 13M consoles in almost 5 years. Today most of the protection of the Wii-U is completely hacked (and can run homebrew code and Linux). Furthermore, Wii-U games can be pirated.

PS4

The PS4 was released in 2013. The PS4 featured dual CPU each with 4 cores (1.6Ghz) and 8 GB of RAM. The hardware was refreshed (and marketed as PS4 Pro) with faster CPU and GPU on 2016. The PS4 design was based on past mistakes and most legacy components were removed. However, the PS4 used the webkit as a browser and FreeBSD as an operating system. Both FreeBSD and webkit are open-source software and both have known weaknesses. These weaknesses were used to hack the PS4 for piracy.

In order to boot Linux and run Homebrew code hackers had to reverse engineer massive part of the hardware and code platform specific parts into the Linux kernel. (Marcan 2016) Lecture details these efforts. Today PS4 can be hacked to run any software included pirated games and other operating systems (Linux). However, unlicensed platforms and operating systems are not allowed on Sony's play station network.

Xbox One

The Xbox One was released in 2013 and competed with the PS4 and Wii-U.

Upon launch, the system had an AMD CPU (1.75Ghz, 8 cores), AMD (ATI) graphics adapter, 8GB of RAM and various hard drive options. The system was re-launched as Xbox One S (August 2016) and Xbox One X (November 2017) featuring faster CPU and GPU, more RAM memory and faster Buses.

The Xbox One S is the most powerful console ever released at the time of writing this chapter. It is estimated that roughly 40M Xbox one units were sold.

The Xbox security is still unbroken (at the time of writing this chapter)

One of the main controversies involved with Xbox One and DRM is the game locking controversy.

A common practice among players is to play a game until one “finishes” the storyline of the game or is tired of it. After finishing the game, the player exchange the game in a local game store for another game or lend it to a friend. Thus, the game now has a new “owner” and a new user can play the game (though only one user can play the game simultaneously). Microsoft toyed with the idea of locking games to specific Xbox Live account eliminating the habit of lending or exchanging games. There was a tremendous public cry when the gamers found out about it (Matricker 2013) and Microsoft eventually backed down (Stuart 2013).

Nintendo Switch

Nintendo Switch (Hereby Switch) is a home/portable console that uses mobile hardware (ARM chips, battery etc.). The switch was unveiled on 2016 and released on 2017. It replaces the unsuccessful Wii-U. The switch offers 8 ARM cores (1 Ghz) Nvidia GPU and 4GB of RAM. It can be used both as a portable or stationary home console.

The Switch sold 23M units in about a year and a half since it was released much more than the Wii-U, that sold 13M units in 5 years.

In December 2017 9 months after the Switch release it was partially hacked by Plutoo et al. (Plutoo 2017) The switch suffers from browser bugs that were demonstrated to attack it. However, at the time of writing this chapter there is no published way to pirate games for the Switch.

SOLUTIONS AND RECOMMENDATIONS

These are common errors that were committed multiple times by multiple vendors.

Any single security mistake may be sufficient to break the security of any single console.

To create an efficient security system the manufacturer should perform a through code audit and ensure past mistakes are not present in the new product.

Security By Obscurity

Common mistake by all the vendors is to underestimate hackers' abilities. In the recent console generations hackers have reversed complex PowerPC code, tapped to the Xbox hyper-transport bus. Hackers resources, especially of modchip makers, should not be underestimated as there is prospering industry in attacking consoles security, especially for piracy.

Furthermore, contrary to common belief security by obscurity works at least partially. It appears that by reusing code from open-source or past projects the console becomes vulnerable to well-known attacks. Also, security by obscurity proved vital in protecting PS3, Xbox one and others.

Not Using Security Professionals

We have seen security mistakes in implementing cryptography by Microsoft, Sony and Nintendo. These security holes resulted in piracy in GameCube, PS3 and Xbox. These mistakes could have been avoided by hiring security experts to review the crypto code.

Community as Means to Reduce Piracy

Most modern consoles offer network-based gaming on their own private networks.

These networks force the users to upgrade to the recent operating systems and prevent downgrading to vulnerable system versions. As a result piracy rate immediately drop.

FUTURE RESEARCH DIRECTIONS

Today most consoles are already hacked. (with limited attacks against Xbox one and switch). Naturally unhacked consoles offer new challenges and interesting research area.

Creating a secure platform (Perhaps for generation 9 consoles) is another important research area.

However, the question of creating a trusted platform with decent DRM features for the mass market consumers has moved from consoles to mobile phones. Creating a phone that cannot be rooted and will create a trusted execution environment is a critical problem that Apple and Google are facing.

There is significant work and publications on rooting mobile phones as creating unbreakable versions. This research has many similarities to game console research as well as some additional challenges such as preserving battery life.

CONCLUSION

All modern game consoles security, except for the PS3 were broken (at least for offline piracy) in very short time. Broken security allowed game piracy hurting manufacturer revenues. We hope 9th generation consoles that will be released soon will pose greater challenge for hackers. We also hope console makers will enable Linux on the console and eliminate some of the motivation to attack the 9th generation consoles.

KEY TERMS AND DEFINITIONS

Boot Loader: A small piece of code that provides minimal functions. The boot loader is executed prior to booting the operating system. The boot loader typically provides minimal hardware drivers, file system support etc. that are required for reading the operating system code.

Chain of Trust: Group of computer components that starts at a trust nexus. Through a series of operations, each component in the chain adds functionality and verifies the next component. Thus, if the nexus can indeed be trusted then the final component can be trusted as well.

Console: An entertainment system designed to play video games (e.g., Microsoft's Xbox or Sony's PlayStation).

Data Execution Prevention (DEP or W^X): A paradigm that dictates that memory pages can have either execute or write permission but not both. Data execution prevention prevents self-modifying code and also attacks on the code that runs by itself (by exploiting buffer overflows and similar attack forcing the code to rewrite itself). DEP is a critical feature in almost all modern operating systems.

Digital Millennium Copyright Act (DMCA): A united state law that defines what constitute of fair use by the end-user and what constitutes as piracy or DRM violation. The DMCA criminalizes production of devices whose sole perhaps is breaking DRM.

Digital Rights Management (DRM): A software subsystem designed to allow rightful users to use contents (games, media) they paid for and disallow illegal use of contents the user has not paid for. DRM is mainly designed to limit the end-user, and as such, DRM software is not liked by the users.

Homebrew: Software that the end-user codes and/or compiles for his own (and his friends) device. This software is not suctioned by the device manufacturer who receives no royalties.

Hypervisor: Software package and hardware support for running multiple operating systems on the same hardware (e.g., VMWare ESXi, Microsoft Hyper-V, etc.).

Modchip: A hardware device that is soldered on top of existing product PCB replacing some chip. Usually, the modchip is designed to remove or disable the chip that handles copy protection.

Trusted Computing (Trusted Systems): Trusted systems are systems that are supposed to behave in a certain predefined way (for example, verify DRM). Local and remote software can attest that the system is indeed a trusted system before executing code.

Puneet Kumar Kaushal

Lucideus Technologies, India

INTRODUCTION

Internet technology and its development have taken us to the next level of evolution (Dingledinel, Mathewson & Syverson, 2004). It has impacted almost every aspect of our lives. But it also has its own disadvantages such as enabling criminals to carry out their criminal operations in any corner of the world without being physically present (Sharma et al., 2018). Due to emergence of innovation in technologies, numerous ways have opened up for illegal trades, one of which is that of drugs.

It is a well-known fact that human beings have been using drugs since time immemorial, but the way they are used remains one of their most confusing behaviours (Evolutionary models of human drug use Wiki, n.d.). Though, fast rate proliferation of drug markets is taking place online with recent evidences suggesting the availability of any drug, they are the so-called cryptomarkets or the dark net markets that have been grabbing eyeballs for the guaranteed anonymity they provide to the users, be they sellers or buyers (Mounteney, Oteo & Griffiths, 2016). Researchers say, “There are now around 50 online market-places on the ‘dark web’ that trade illegal drugs, new psychoactive substances (NPS), prescription drugs and other – often illegal – goods and services” (Kristy, 2016). The internet has drastically changed the ways of doing business, including those of illegal markets.

Many organizations generate backend data that is dynamically retrieved through Web-form-based interfaces and thus not indexed by conventional search engines and this hidden, invisible, and unindexed content is called the Deep Web (Jung, Chun & Geller, 2008). The websites that form a part of the deep web cannot be accessed through the conventional search engines and requires specific software and configurations (Sharma et al., 2018). These sites contain the thoughts and ideas of many secret organizations, groups, and individuals who want to remain anonymous (Broséus et al., 2017). The dark web is a small portion of the deep web that is used mainly for illicit activities, because of the anonymity it offers it to its users (Mounteney, Oteo & Griffiths, 2016).

In order to venture into the deep web, a user will have to download a special browser which hides a website’s identity or IP, such as The Onion Router or TOR. As per the experts, “TOR encrypts web traffic in layers and bounces it through randomly-chosen computers around the world, each of which removes a single layer of encryption before passing the data on to its next hop in the network” (Greenberg, November 2014).

Cryptomarkets also involves financial aspects and thus, these markets also need to have some special forms of currency to provide a substantial level of anonymity. This is done by using cryptocurrencies such as Bitcoin (Cox, 2016). The present paper lays focus on this new means of acquiring illicit drugs from the markets available on the dark web, how these so called cryptomarkets have evolved through the use of technology to evade law and enforcement, their future and the role of governments in preventing this version of drug trafficking.

DOI: 10.4018/978-1-5225-9715-5.ch032

BACKGROUND

Drugs are defined as all substances and chemicals that should not be used for any purpose other than for medical and scientific research; if they are used for purposes other than these, they are called illicit drugs (Kassaye, 1999). Drugs are as old as human history and have been used for a variety of reasons in plethora of cultures; for religious purposes, for entertaining purposes, for altering the states of consciousness, as a matter of proud and for obtaining relief from pain, sadness and distress (Parmar et al., 2015). The black trading of drugs starts developing in jurisdictions where the law prohibits or restricts their sale (Drug trafficking, 2017). United Nations Office on Drugs and Crime defines drug trafficking to be a global illicit trade involving the cultivation, manufacture, distribution and sale of substances which are subject to drug prohibition laws (United Nations Office on Drugs and Crime, 2017). Several studies and researches have been conducted on the illegal trade of illicit drugs on the dark net. Martin gives a detailed description of the illegal drugs trade on the dark web, presenting the concepts of cryptomarkets and their commercial operations, analyses online and offline markets and discusses and suggests law enforcement practices (Martin, July 2017).

On the other hand, Buxton & Bingham explain that how the online drug trafficking reduces the scope of violence that occurs in traditional drug markets and how this approach can lead to dedication of resources towards more serious cybercrimes (Buxton & Bingham, 2015). Studies such as (Broséus et al., 2016), (Europol, November 2017), (Kruithof et al., 2018) and (Phelps and Watt, 2014) are area-specific, and analyse the situations in the respective regions. Some others analyse various cryptomarkets. Silk Road, the largest online drug market has been a topic of discussion in several papers (Aldridge & Décary-Héту, 2014; Barratt, 2014). The geographical analysis of Agora and Evolution has been performed in (Dolliver et al., 2018) and (Broséus, 2017) respectively. Cox talks about how feedbacks and ratings impact the reputation of the vendors on cryptomarkets (Cox, 2016). Aldridge and Décary-Héту have tried to project the future of the illicit drug markets (Aldridge et al., 2016). The same has been presented by Mounteney, Griffiths and Vandam (Mounteney, 2016). The market of illegal drugs, be they produced in laboratories or grown naturally, is gigantic and it is estimated that the annual global trade is worth \$321 billion (Drug trafficking, 2017).

Today, majority of the countries in the world are getting trapped in the vicious circle of drug abuse and trafficking with the number of drug addicts increasing day by day due to many socio-economic reasons such as unemployment, poverty and socio-political disturbances (Parmar et al., 2015). Figure 1 shows the number of people by age, worldwide, as reported by the UNODC Report 2018 losing their lives due to drug use during the time period 2000-2015.

DARK WEB, DEEP WEB AND 'THE ONION ROUTER'

As per the experts, “searching on the internet today can be compared to dragging a net across the surface of the ocean. While a great deal may be caught in the net, there is still a wealth of information that is deep, and therefore, missed (Finklea, July 2017).” Thus, internet can be thought of as composed of two parts: one is the “Surface Web” and the other is the “Deep Web”. The Deep Web refers to “a class of content on the Internet that, for various technical reasons, is not indexed by search engines” (Finklea, July 2017). The dark web lies in the farthest corners of the deep one and is infamous for harbouring criminal and illegal activities such as trafficking of drugs, sex and humans, child pornography, sale of arms and weapons, sale of exotic animals and other illegal goods and services. The websites on dark

Figure 1. Deaths resulting from drug use disorders, by age group, worldwide, 2000-2015

Source: United Nations Office on Drugs and Crime (UNODC), World Drug Report 2018

web are intentionally hidden. At the same time, due to the privacy it offers, it is a hub for military, law enforcements, journalists, human rights activists, political leaders, reformers and many other organizations/individuals. Barratt further categorizes the content on deep web into five categories. (Barratt, 2018).

Onion routing was developed in the mid-1990s by three employees of the United States Naval Research Laboratory with the purpose of protecting the U.S. intelligence communications online and it was further developed by DARPA in 1997 (TOR (anonymity network) Wiki, 2018). The Onion Routing project, or Tor project was launched on 20 September 2002 (TOR (anonymity network) Wiki, 2018). As noted by the torproject.org, “The Tor network is a group of volunteer-operated servers that allows people to improve their privacy and security on the Internet. Tor’s users employ this network by connecting through a series of virtual tunnels rather than making a direct connection, thus allowing both organizations and individuals to share information over public networks without compromising their privacy” (The Tor Project Inc, 2017). Onion Routing is a distributed overlay network designed to anonymize TCP-based applications like web browsing, secure shell, and instant messaging wherein the users choose a path through the network and build a circuit, in which each node (or “onion router” or “OR”) in the path knows its predecessor and successor, but no other nodes in the circuit (Dingledine et al., 2004). The TOR network and the underlying TOR browser are based on Onion Routing. The TOR is an open source project and can be downloaded from the internet.

The use of TOR browser reduces the risk of what we call traffic analysis. Traffic analysis has been defined as “the process of intercepting and examining messages in order to deduce information from patterns in communication. Traffic analysis can be performed in the context of military intelligence or counter-intelligence, and is a concern in computer security” (Northcutt, May 2007). TOR also provides communications which are least prone to eavesdropping.

In the TOR network, relays are known as the computers that switch traffic from one computer to the other. There are around 7000 computers in the TOR network. All the relays run the TOR software, and this enables them to interact with every other relay (simply a computer) that is a part of the TOR network. So when any source wants to connect with a destination, a circuit is created. A circuit can be thought of as a path through which the traffic flows, right from the source to the destination. Every circuit in the TOR network lives for few minutes and after that it is pulled down and re-established by choosing a different set of relays. This is also known as virtual circuit. In this network, some computers or relays are special, and they are called as directory authorities. Their responsibility is to maintain a list of all possible relays at any given moment. The TOR browser then downloads this information and

builds a list of relays to choose from for communicating. The traffic flows through a minimum of three relays - the guard relay, the middle relay and the exit relay; each relay knows from which relay the traffic has arrived and to which relay it has to be sent but the complete circuit remains anonymous to each of the relays (Hassan, 2017).

The relays are publically listed in the TOR directory. As per (What is TOR?, n.d.), there are three types of relays - middle relays, exit relays and bridge relays. The first two relays are called the middle relays and play an important role in adding to the speed and robustness of the TOR network; they “advertise” themselves so that any other relay in the TOR network can connect to them. An exit relay is the one through which the traffic flows the last, before reaching its final destination and as they are second last in the circuit, are prone to being interpreted as the source of the data (What is TOR?, n.d.). Though relays are publicly listed in the TOR directory, there are some relays that are not. These are defined as “bridged relays”. In (What is TOR?, n.d.), they have been defined as “essential censorship-circumvention tools in countries that regularly block the IP addresses of all publicly listed TOR relays, such as China.”

In addition, TOR network also enables setting up of hidden services. This is the ability to anonymously host and browse content and services within a vast address space (Lewman, 2016). The first step is the installation of TOR and configuring the hidden service. Next, the hidden service has to advertise itself over the TOR network. For this, it randomly picks relays or so called ‘introduction points’ and establishes circuits with them. To receive connections, a hidden service descriptor is assembled which contains its public key and summary of each introduction point. Hidden service signs this with its own private key and it is uploaded on the directory servers. The descriptor will be found by clients requesting abc.onion where abc is 16 character name derived from its public key. Any client who wishes to contact the hidden service must know its onion address first. Then, the client downloads the descriptor from the directory authorities and gets to know about the public key and the set of ‘introduction points’. The client also picks a relay as ‘rendezvous point’ randomly and tells it one-time secret. When the descriptor is present and the rendezvous point is ready, the client prepares an introduce message containing the address of the rendezvous point and one-time secret and encrypts it with the public key of the hidden service. The client sends this to one of the introductory points which forwards it to the hidden service. Then, the hidden service decrypts it with its own private key and obtains its contents – the address of the rendezvous point and one-time secret. The hidden service creates a circuit to the rendezvous point and sends the one-time secret to it. Finally, the rendezvous point notifies the client of the successful connection establishment. The rendezvous point now simply forwards data between the client and the hidden service. A post by the TOR Project looks at the volume of hidden services traffic and estimates that there are around 30,000 active hidden services serving around 5 terabytes of information on a daily basis (Lewman, 2016). A sensational darknet marketplace that operated on TOR as a hidden service was Silk Road, created with a custom-generated domain name silkroad6ownowfk.onion.

SILK ROAD

Silk Road was founded in February 2011 by ‘Dread Pirate Roberts’ or DPR – a pseudonym that stood for either a person or a group of persons. Born in Austin, Texas, Ross Ulbricht is believed to be the man behind DPR and Silk Road. It was a haven for drug dealers, gun runners and document forgers and has been described as the internet’s Wild West and the eBay of vice (Norry, 2018).

Till its shut down by FBI in October 2013, Silk Road grew from an underground black market known by few, to a slick commercial enterprise that had been accessed by over a million people; it is estimated

that, in a little under three years, the site's users spent on a range of drugs: cannabis, prescription drugs, MDMA, LSD, heroin, crystal meth and every other illicit drug (Ormsby, 2016). All the communications were anonymized by the TOR browser, and the drugs were purchased online from vendors displaying eBay-style shop fronts and delivered through the post (Aldridge & Décary-Héту, 2014).

Researchers explain that 65% of the listings on Silk Road were related to the illicit drug trade which corresponded to around 13,000 listings for controlled substances, including opioids, precursors and stimulants while the other listings included 'services' mostly concerning computer-hacking; 'digital goods' such as pirated media content; and 'forgeries', predominantly fake identity documents (Hassan, 2017). Transactions used to take place in untraceable peer-to-peer cryptocurrency known as Bitcoin and the marketplace followed a strict system of escrow: payments weren't released to the vendors until the buyers were satisfied with the purchases. When Silk Road was shut down, FBI determined that over \$1.2 billion in sales had occurred involving 150,000 customers and 4000 vendors (Chertoff, 2017).

The Silk Road had always been characterized by the journalists, academicians and media as a resemblance to "business-to-customer" e-commerce platforms. But when some researchers downloaded 12000 listings on Silk Road together with profile pages of around 1000 vendors listing them, it was apparent that "many vendors were selling in quantities, at prices, and using terminology suggesting that they were knowingly selling to customers intent on resale: to customers who were themselves drug dealers" and arrived at the conclusion that "Silk Road was an online marketplace catering primarily to those making purchases for resale; that is, to street drug dealers buying stock to sell offline and to illegal drug manufacturers purchasing the products and services allowing them to synthesize illegal drugs" (Aldridge & Décary-Héту, 2014).

Some interviews conducted just after closure of Silk Road revealed that for some, the closure was a "catastrophe", for some it was "little more than temporal inconvenience", some had formed cordial relations with the vendors and carried out transactions through secured email bypassing the black markets altogether and others said they would return to the traditional methods of acquiring drugs (Ormsby, 2016).

But this crack down didn't stop the emergence of new cryptomarkets on the darknet throughout 2014. Just after 35 days when Silk Road was closed, Silk Road 2.0 came up and it was launched by the former Silk Road site owners. Several other darknet markets such as Pandora, Agora, Hydra, Evolution and Silk Road 2.0 competed with each other to win back the trust of the sellers and the buyers.

On 5 November 2014, 'Operation Onymous' was launched which as per Europol, was a joint initiative taken by the law enforcement and judicial agencies around the globe, coordinated by Europol's EC3, the FBI, ICE, HIS and Eurojust against "dark markets running as hidden services on the Tor network, aimed to stop the sale, distribution and promotion of illegal and harmful items which were sold on online dark marketplaces" as a result of which "410 hidden services taken down, 17 vendors and administrators arrested, and USD 1 million worth of Bitcoins, EUR 180,000 in cash, drugs, gold and silver seized (Europol, 2013)." Operation Onymous resulted in the closure of a number of cryptomarkets: Pandora, Silk Road 2.0, Black Market, Blue Sky, Tor Bazaar, Topix, Hydra, Cloud 9 and Alpaca (Europol, November 2017). The perpetrators didn't halt, again after 35 days of crack down of Silk Road 2.0, Silk Road 3.0 came up and is present on the dark net till now. There are still near about 14 marketplaces that appear to be operational and carrying out the black trade of illegal drugs: Valhalla, Dream Market, Silk Road 3.0, T•chka, Darknet Heroes League, Apple Market, House of Lions Market, TradeRoute, Wall Street Market, RSClub Market, Zion Market, Innite Market, CGMC and OW Market (Europol, November 2017).

THE ROLE OF CRYPTOCURRENCIES AND ENCRYPTION IN DARKNET MARKETS

Cryptocurrencies are used to carry out transactions on the Dark Web. These are decentralized and digital currencies that use anonymous, peer-to-peer transactions. For many years now, Bitcoin has been the primary facilitator of notorious drug transactions in the cryptomarkets. It allows anonymous buyers to pay the anonymous vendors in the absence of a proper, centralized financial system such as banks and is as difficult as TOR to be traced. Bitcoin is an “online virtual currency based on public key cryptography”, and was published in 2008 in a paper titled “Bitcoin: A peer-to-peer Electronic Cash System”, authored by someone behind the Satoshi Nakamoto pseudonym (Herrera-Joancomartí, 2014). As per bitcoin.org, “Bitcoin is open-source; its design is public, nobody owns or controls Bitcoin and everyone can take part” (Bitcoin, n.d.). Bitcoins are stored in “encrypted digital wallets” and are very difficult to be traced back once the transaction has been made (Chertoff, 2017). This happens because the transactions being made are though stored in a public ledger, only the addresses of the wallets and not the credentials of the persons owning them are stored. This ledger is called the blockchain.

Blockchain is equivalent to a bank statement, except it keeps track of the whole currency, rather than just an individual’s account (Cox, 2016). The blockchain is freely replicated and stored in different nodes of the bitcoin network, making it a completely distributed system (Herrera-Joancomartí, 2014). Blockchain also helps in mitigating “double spending problem” since it contains the history of all past transactions, where one can publicly see the amount of bitcoins or currency owned by each user.

Transactions can be thought of as lines in a double-entry bookkeeping ledger; each transaction contains one or more “inputs” which represent debits against a bitcoin account, there are one or more “outputs”, which are credits added to a bitcoin account and the outputs add up to slightly less than inputs as some small payment is collected by the miner who includes the transaction in the ledger (Antonopoulos, 2014). Blocks join together to give rise to blockchain and experts define a ‘block’ as a “series of updates of the transfers between addresses, as a fresh page in the ledger containing information about the block exactly preceding it” (Cox, 2016). A transaction is said to valid or successful if a block containing that transaction gets included in the blockchain.

There are two ways of obtaining bitcoins. One would be to buy them in exchange of traditional currencies by logging in to bitcoin exchange and other would be to ‘mine’ them. Adding a block to the blockchain is known as mining. Mining can be done by any user of the Bitcoin network using special software and hardware. Each block contains a tough mathematical problem that need to be solved before that block gets added into the Blockchain. So how is it done? “The mining process makes use of a proof-of-work system consisting of finding a hash of the new block with a value lower than a predefined target” (Herrera-Joancomartí, 2014). The miner who finds the solution for a block first is given some bitcoins as rewards. As mining is a very important part of the Blockchain system, miners also receive awards in the form of fees that each transaction pays to the miner. The role of public key cryptography in the Bitcoin system is presented below (Antonopoulos, 2014):

In Bitcoin, public key cryptography is used to generate a pair of keys, which control the access to Bitcoins. They are stored in the wallet of each user. This pair consists of a private key used to sign transactions to spend Bitcoins and a public key to receive Bitcoins. So in a way, these keys enable a user to prove the ownership of funds for transaction in the Bitcoin network, unlock the value to spend and transfer it to a new recipient. The private key is a randomly chosen 256-bit number and a one-way cryptographic function called elliptic curve multiplication is used to generate a public key. The Bitcoin address is also

generated from the public key using one-way cryptographic hash function. It is a string of digits and characters that can be shared with anyone who wants to send you money.

As per a *chainanalysis.com* report on the use of Bitcoins titled “Darknet markets are no longer a major use of Bitcoins”, it turns out that in 2017, more than \$660 million of Bitcoins were sent to the cyptomarkets and that is a more than 11-fold increase from the \$57 million sent to darknet markets in 2012, when the Silk Road, the first darknet market, was becoming popular (Chainalysis, 2018). At the same time it also reports that in March of 2012, nearly 30% of all Bitcoin transactions were being sent to darknet markets, but in 2017 this declined to less than 1% mainly because of three reasons, law enforcement closed the major darknet markets, Bitcoin became a financial asset, “crowding out its use as a means of illicit exchange” and new cryptocurrencies such as Monera, Zcash and Dash arose, providing greater anonymity and lower transaction fee.

Due to the illicit nature of the businesses conducted in the cryptomarkets, and to maintain anonymity, the administrators, buyers and vendors encrypt their communications using some encryption programme. Most commonly used one is PGP or “Pretty Good Privacy”. PGP was created in 1991 by Phil Zimmermann and is a computer programme that allows encryption of messages and files so that only the intended recipient is able to decrypt it and no third party can interpret the communication taking place between the two. PGP works as follows (Cox, 2016):

In this system, every user possesses two keys: a public key and a private key. These keys are files that could be stored on user’s computers. The public key is the one that is used to encrypt. Private key is used to decrypt. Private key must be kept secret ideally as it is used to decrypt any messages or files encrypted for a user, as well as signing any messages the user sends, to assure the recipient that they are indeed communicating with is the correct person. To use the encryption protocols, the user usually makes use of a special programme that has simple buttons such as ‘encrypt’, ‘save’ and others. The user types in the plaintext, chooses a public key that corresponds to the recipient, encrypts and finally sends it. Even if law enforcement agencies or the provider of email services intercept these messages, it is impossible to intercept the contents as long as the private key is not available.

DRUG TRAFFICKING ON DARK WEB

As already discussed, technology to maintain anonymity is being used to the fullest to commit illegal activities on the dark web. It is difficult for the law and enforcement to trace these activities. Billions of dollars are created by these businesses on the dark web and with passing days, they are flourishing. Several researches have been conducted on the kind of drugs being sold on the types of drugs being sold on the dark web websites. During 2016, the data and information collected and analysed by some researchers in aimed to focus on various aspects of the nature of drug trafficking on eight major cryptomarkets existing at that time, revealing that the number of transactions had tripled since the shut-down of Silk Road in 2013, revenues had doubled, listings placed by vendors played a major role to initiate the transactions, vendors from the USA dominated the cryptomarkets and the drugs which were sold the most were predominantly cannabis, followed by stimulants and ecstasy-type drugs (Kristy, 2016). As per the United Nations Report 2018, authorities in Europe has revealed some shocking statistics: “drug sales on the darknet from 22 November 2011 to 16 February 2015 amounted to roughly \$44 million per year but a later study estimated that, in early 2016, drug sales on the darknet were between \$14 million and \$25 million per month, equivalent to between \$170 million and \$300 million per year (United Nations

Office on Drugs and Crime, 2018).” Analysis of transactions done for various kinds of drugs done by Kruihof and others revealed some sort of stability, though, some changes were also observed (Table 1).

It was revealed that the rate of increase in vendor numbers across larger markets was consistent with Alphabay and Dream market being the largest of all the markets (Van Buskirk, 2016). It disclosed that in these two marketplaces, cannabis, pharmaceuticals, MDMA, cocaine and methamphetamine were the most famous and the popularity of NPS declining. In July 2017, major cryptomarkets Alphabay and Hansa, both TOR-based, were shut down. Alphabay was said to be ten times larger than Silk Road with around 250,000 listings on AlphaBay, 200,000 members and 40,000 vendors. On the other hand, Hansa had around 3,600 dealers who offered more than 24,000 drug product listings, from cocaine to MDMA to heroin (Greenberg, 2018). Several dark net markets still exist and are carrying the black trade of drug trafficking (Table 2). One an order is placed and payment to the vendor held in escrow, drugs are packed into vacuum seal packets and due care is taken to not leave any fingerprints or traces of DNA by dipping them in a bleach solution (Economist, 2017). The packets are labelled with printed labels and posted via far off post offices (Economist, 2017). According to criminologist James Martin, “reducing the violence of a bloody drugs war; promoting safer drug-taking practices through online forums; and supplying purer drugs, with fewer potentially deadly adulterants” are the major reasons behind the drug trade on the dark net (Martin, July 2017).

The extent to which users buy illegal drugs online can be analysed by numerous surveys conducted. Figure 2 shows the rise in number of drug users who had ordered drugs online in past 12 months, 2014-2017, clearly reflecting around 69% increase during this period.

Table 1. Number of transactions of various substances and their market share on the darknet, September 2013 – January 2016

Drug	Transactions September 2013	Transactions January 2016	Transactions in percentage: September 2013	Transactions in percentage: January 2016
Cannabis	10,663	30,790	31%	33%
Stimulants	4,898	17,206	14%	18%
Ecstasy-type	3,982	11,031	11%	12%
Prescription drugs	6,612	17,984	19%	19%
Opioids	2,015	5,241	6%	6%
Other drugs	735	465	2%	< 1%

Table 2. Drug listings in the major operating cryptomarkets

Name of the darknet market:	Onion URL:	Total Listings	Drug listings
Dream market	http://4buzlb3uhrjby2sb.onion	62,834	59,108
Wall Street	http://wallstyizjhkrvmj.onion	12,032	5,469
Point/Tochka Free Market	http://tochka3evlj3sxdv.onion	7,975	3,575
Silk Road 3.1	http://silkroad7rn2puhj.onion	51,829	31,633

The results of an eleven-month long web crawling procedure implemented on daily basis by researchers on Silkkitie, the Finnish version of the Silk Road from November 2014 to September 2015 revealed in 2017 that the most famous drugs bought over this dark net market were stimulants and they were followed by cannabisproducts, empathogens such as MDMA and psychedelics (Nurmia et al.). Silkkitie was opened on 6th January on 2014 and was meant for purchase of sale and purchase of drugs in Finland only. This market facilitated smooth operations in Finland as there was no fear of being caught due to no security checks or screening anywhere. The extensive research over 93,878 observations of 260 sellers offering 3823 products. As with other markets, it also highlighted that higher were the positive feedbacks, higher were the sales, with the total sales of 41,131 items worth 171,387 Euros. As per Décary-Héty et al (2018), herbal cannabis, which is considered to be quite expensive in the USA, accounted for 21% of all sales observed on cryptomarkets, generating total revenue of US\$3.1 million per month. The customer discussions on a forum named drugs-forum.com revealed the sale of cocaine e-liquid in its free base form or crack cocaine freely available on dark web. Nichols (2018) says that Japanese drug dealers even offer free samples and give refunds if the customers are not happy with their purchases.

SOLUTIONS AND RECOMMENDATIONS

It is the need of the hour to devise policies to facilitate a more holistic approach in the detection and intervention of online drug trade. Numerous challenges are being faced by the law enforcement, such as, high resistance to take downs, crimes are committed in remote locations, the communications are encrypted, cryptocurrencies are used, presence of alternative banking platforms and utilization of cloud technologies (Phelps and Watt, 2014). Cox presents seven ways by which the police can track down anyone on the deep web, and these are, going underground, hacking, open source information, mass surveillance, digging through seized data, following the money and the postal system (Cox, January 2016). Hayes, Cappa and Cordon successfully tested a Web crawler using AppleScript for scraping dark web marketplaces that can be used to gather information about the numerous vendors and their listings on the dark web and can be of great importance for the investigators examining the criminal activity on it (Hayes et al., 2018). Michael Chertoff and Tobby Simon in (Koebler, February 2015) have

Figure 2. Annual drug users obtaining drugs over the darknet in the past 12 months, 2014-2017

Source: United Nations Office on Drugs and Crime (UNODC), World Drug Report 2017

devised some methods that can be used to scan the dark web. According to them, researchers should find “new ways to spot upcoming malicious [dark net] services to deal with new phenomena as quickly as possible.”According to them, monitoring customer data, hidden services and social sites, mapping the hidden services directory by operating the TOR network nodes, marketplace profiling and semantic analysis can aid in cracking anonymous nature of dark web and the illegal trades happening over it. It is the lack of correct knowledge, training and understanding of the deep web that serves as a barrier for the law enforcement to venture into the deep web and wage a war against them. The anonymity that deep web offers can be treated as an advantage rather, if they enact themselves as children, dealers or any other potential victims and start sitting in the chat rooms to monitor conversations (Lewman, 2016). De-anonymising the users of deep web and exploiting user mistakes will also aid in catching the criminals (Lewman, 2016). Economist recommends the law enforcement to continue the ongoing work against the major cryptomarkets emphasising on their administrators and moderators, find strategies to dismantle the trust existing between the vendors and the buyers and dismantle cryptocurrency that makes it possible to make and receive payments for drugs (Economist 2017). The existing scenario is a matter of big concern for the governments worldwide. Law enforcement is trying its best to curb this menace. The changing phase of the internet and technologies is enabling the criminals to go digital, and exploit nations’ resources. Continuous monitoring will be the best possible way to crack down the cryptomarkets. The governments and law enforcement authorities should train their agents to master the new technologies. If they would know the modus operandi of the cryptomarkets, they would know the methods to shut them down as well.

FUTURE RESEARCH DIRECTIONS

Only monitoring the websites that undertake drug trades is not going to be sufficient till the time we get to know that which type of substances are being used by whom. Drug user forums can be considered to be the rich sources of information, they themselves being online markets provide access to a large population of drug users than was available to the researchers earlier (Mounteney, 2016). It needs to be seen that how “balloon effect” happens, that is, how it has been a trend that when any market is taken down, new markets turn up in its place within so short periods of time. The postal systems are considered to be the fuel of these running engines. Though the buyers and vendors don’t ideally meet with each other in person, the postal systems deliver the drugs unknowingly to the buyers. Therefore, the role played here by post offices needs to be observed. The methodological issues regarding researching the deep web also widen the scope of research based on ethnography pertaining to drugs usage, sale and purchase accompanied with netnography and infodemiology (Mounteney, 2016). Tools and software need to be developed that can break the anonymity of the deep web. The role of social media needs to be analysed. Not only this, more clarity is needed as to why people move to online drug markets, what are the differences between the profiles of online vendors and the street dealers, how do quantities bought and sold on dark net actually look like and how do online markets interact with offline ones regarding the supply chain (European Commission Directorate-General Migration And Home Affairs, n.d.). The trade needs to be viewed and researched from every angle, starting from the growing relationships between vendors and buyers online, to delivery of the products and during the payment phase. Gwern Branwen, a researcher, web-crawled roughly 90 dark net places from December 2013 to July 2015 and gathered around 1.5 terabyte of data from 360,000 websites, “on the items sold, the Bitcoin price of the item, the date of the sale, shipping information, customer ratings and the vendor’s pseudonym” (Gwern et al., July 2015).

Not only this, Gwern in his studies also said the data set contains various vendor PGP keys, username (even clearnet names), and email addresses (Gwern et al., July 2015). Such researches in the future can be of great importance to shed some light on the deep web but as far as internet is concerned, the pace at which it is developing and evolving, it will always pose threat to the governments, law enforcements, research agencies and most importantly, mankind.

CONCLUSION

Internet has been a revolution in our lives. As it has got no geographical and international boundaries and can be accessed anywhere from the world, the number of internet users has increased drastically. This has led to increasing instances of severe cybercrimes. Cybercrimes have become extremely threatening and challenging crimes to be checked by the law and enforcement. Criminals are using the advancements in technology to their advantage. Mobile devices provide additional opportunities to carry out criminal operations while sitting in any corner of the world. It is difficult to nab the culprits as these crimes occur almost instantaneously and the enforcement agencies are ill-equipped and lack expertise. Various crimes such as identity theft, forgeries, child pornography, sex and human trafficking, terrorism and drug trafficking among others get efficiently planned and executed over a special and small part of the internet, called as dark web. It is indispensable to keep on researching and analysing both the dark web and deep web to keep an eye on the operations of the criminals and to allow adoption of new methodologies to reduce such malicious opportunities on the cyber space. As we have seen that drug trafficking has swiftly shifted from the streets to the cryptomarkets due to anonymizing browsers such as TOR, encryption, cryptocurrencies and increasing demand for illicit drugs, it becomes very important to shape laws and policies to combat this form of illegal trading on cyber platforms for the betterment of the society. In addition to this, international cooperation and coordination can play a major role in deploying these to tackle this internet facilitated drugs trade.

KEY TERMS AND DEFINITIONS

Block Chain: As the name suggests, block chain is a chain of blocks that serves as a public ledger of the Bitcoin network revealing ownership information of all the addresses. It is like a data file that contains the history of all the Bitcoin transactions that have taken place till now. Every block is based on its predecessor and contains information about the new transactions that got validated through it.

Cryptocurrency: It refers to any digital currency that uses certain encryption methods to secure and validate the transactions and generate new currency of its own kind.

Cryptomarkets: A cryptomarket may be defined as a platform for exchange of goods and services, both legal and illegal, on the dark web. They remain hidden from the world due to the use of anonymizing browsers such as TOR based on encryption techniques. Majority of the cryptomarkets undertake the sale and purchase of drugs.

Dark Web or Dark Net: Dark web can be defined as that miniscule portion of the deep web and hence the internet composed of websites whose IP addresses are intentionally hidden from the public using anonymizing tools such as TOR.

Drugs: A drug can be defined as any substance, chemical or natural, that is consumed for purposes other than medicinal and scientific.

Surface Web: It can be defined as that portion of the internet whose websites are indexed by search engines such as Google, Yahoo, and others. They are easily accessible and do not require the use of special software as needed for the deep web.

TOR: TOR or the onion router is free downloadable software that hides the IP addresses of the computers and hence lets its users protect their identity from traffic analysis.

Virtual Circuit: Virtual circuit is a path for the flow of data packets over a network, which does not exist in reality. It is 'virtual' in the sense that there is no dedicated physical layer link between the source and the destination of the data.

Domain-Specific Search Engines for Investigating Human Trafficking and Other Illicit Activities

Mayank Kejriwal

University of Southern California, USA

INTRODUCTION

Web advertising related to Human Trafficking (HT) activity has been on the rise in recent years (Szekely et al., 2015). Question answering over crawled sex advertisements to assist investigators in the real world is an important social problem. This problem involves many technical challenges (Kejriwal & Szekely, 2017c). This article will describe the problem of *domain-specific search (DSS)*, a specific set of technologies that can address these challenges. Modern DSS systems for investigative activities draw on cutting-edge techniques developed over three years of DARPA-funded research conducted in collaboratively academic (e.g., the University of Southern California's Information Sciences Institute), government (e.g., NASA's Jet Propulsion Laboratory) and industrial (e.g., Uncharted) settings. Evidence from the HT domain shows that the systems can be used to provide valuable utility to analysts and investigative experts.

In illicit domains such as HT but also others like securities fraud and narcotics, domain-specific search involves a form of *Information Retrieval (IR)* that takes as input a large *domain-specific* corpus of pages crawled from the Web. The system allows investigators to satisfy their information needs by posing *sophisticated queries* to a special-purpose engine. A workflow of this process is shown in Figure 1. Since investigators are largely non-technical, they must be able to issue such queries to (and receive responses from) intuitive, graphical interfaces. A fully functional DSS engine must have some notion of semantics, since sophisticated queries go beyond just keyword specification. This is because investigative queries are more like real-world questions requiring complex operations like aggregations (e.g., *find me all email addresses linked to the phone 123-456*).

A viable solution to the problem has to allow the user to pose queries both intuitively and interactively.

For such a DSS to operate semi-automatically and be useful in the real world, several challenges and desiderata must be fulfilled. Possibly the most important of these is handling the unusual nature of an illicit domain, since investigators who have to use the system have special needs. To understand why this can be challenging, consider the recent advent of technologies like neural networks and deep learning. Pre-trained tools such as word embeddings and Named Entity Recognizers in the natural language processing community have also been released for public use (Pennington, Socher & Manning, 2014). However, many of these tools have been trained on datasets and corpora that are fairly 'regular' i.e. comprise of relatively well-structured text (like news corpora and Wikipedia articles). Consequently, they are not necessarily suitable for language or data acquired in illicit domains. Table 1 illustrates some examples of real text scraped from sex advertisement webpages (but with identifying phone numbers appropriately modified). Acquiring and labeling data from such domains is both expensive and sensitive,

DOI: 10.4018/978-1-5225-9715-5.ch033

Figure 1. A procedural workflow of domain-specific search from the point of view of an investigative user, using the domain-specific insight graph (DIG) DSS for example interfaces

3

not easily amenable to crowdsourcing (Kejriwal & Szekely, 2017a). A purely machine learning-based approach is simply not feasible.

Furthermore, the challenge of building a DSS is compounded by the fact that many of the component Artificial Intelligence (AI) tools and methodologies still haven't come close to achieving high-quality human-level performance. These tools span areas like NLP and Semantic Web, and in a real-world architecture, need to operate in tandem. In unusual domains with irregularities, noise is inevitable at every stage of the process and has to be dealt with, rather than assumed away, in the design of the architecture itself. This requires multiple measures of robustness, and a careful understanding of what kinds of noise the end-user (investigators) would find acceptable. Imprecise or careless design can lead to the problem of cascading errors, making a full system unusable.

Over years of careful research funded under the DARPA Memex program, an end-to-end architectural framework has been developed as an admissible and principled way of building an end-to-end DSS for illicit domains, with particular emphasis on human trafficking. One instantiation of the architectural solution, available as both open source code and executable in a stand-alone Docker container, is the *domain-specific insight graph* or DIG system that was built at USC ISI. DIG was rigorously evaluated on real-world data collected from over 90,000 sex-advertising webpages collected over the first half of 2016 (Kejriwal, Szekely & Knoblock, 2018). The principles behind DIG have been replicated independently by an industrial team. Along with other DARPA projects, DIG has been used to prosecute traffickers in the US, and to rescue trafficking victims. Recently, an engine of this type was being used by over 200 law enforcement officials to fight the overall problem of sex trafficking and related illicit activities.

This encyclopedic article will describe the background, main principles and challenges of building a DSS in illicit domains, with a strong focus on human trafficking promoted through illicit sex advertisements on the Open Web. The article will conclude with a description of promising avenues for future research.

BACKGROUND

Building domain-specific search engines for non-traditional domains requires synergies across a range of areas, knowledge graph construction (KGC), machine learning and analytics (especially using intuitive interfaces), and information retrieval (IR). Although a complete review of these fields is beyond the scope of this article, we synthesize core elements below.

Table 1. Example fragments of text extracted from real-world illicit sex advertisements. Note that identifying information has been replaced. Information that is potentially useful to investigators and/or to a semantics-aware domain-specific search engine is highlighted in bold.

Information Integration (II)

Information integration, also commonly known as *data* integration, is generally defined as the problem of providing a unified query interface over multiple data sources (Lenzerini, 2002). Information integration has been a research subject for at least 40 years (El-Masri & Wiederhold, 1979); recent developments and foundational principles are synthesized in the book by Doan et al. (2012). The problem has gained importance with the advent of Big Data (Dong & Srivastava, 2013), in domains ranging from enterprise to computational biology and Web search (Gupta et al., 2013; Brambilla, Ceri & Halevy, 2013; Gomez-Cabrero et al., 2014; Loshin, 2013). Despite the enormous progress in information integration over the last few decades, there are some key challenges in the HT domain that preclude a direct adaptation of many existing techniques. These challenges will be described later in the article.

Information Extraction (IE)

Information extraction is a core component of any information integration and Knowledge Graph Construction (KGC) pipeline over Web corpora, as the unstructured webpages must first be structured in order for fine-grained queries to be executed over them. With the initial advent of the Web, wrapper induction systems had proved successful for several IE domains (Kushmerick, Weld & Doorenbos, 1997). Influential work in the early 2000s e.g., STALKER (Muslea, Minton & Knoblock, 2003) used machine learning methods for the wrapper induction problem (Lerman, Minton & Knoblock, 2003). Such methods were inherently data-driven, and were less brittle than rule-based wrapper architectures. More recent Web information extraction systems include the approach by Barrio and Gravano (2017), and Martinez-Rodriguez, Hogan and Lopez-Arevalo (2018).

IE systems have continued to evolve since then; Chang et al. (2006) provide a comparative survey of many of the leading IE techniques along three dimensions (task domain, degree of automation and the actual techniques used), a key finding being the dependence of techniques on the actual input format. More recently, deep learning and other modern machine learning methods have been applied to domain-specific IE, in domains as diverse as cancer pathology, healthcare and social manufacturing (Qiu et al., 2018; Leng and Jiang, 2016)

More recently, OpenIE has become a popular topic of research, owing to the need for IE techniques that do not rely on pre-specified vocabularies (Etzioni, Banko, Soderland & Weld, 2008), but this work is largely orthogonal to advances in DSS, since the vocabulary and domain have to be specified. For more recent advances in Open IE, we refer the interested reader to the work by Bhutani, Jagadish and Radev (2016), Angeli, Premkumar and Manning (2015), and (in the case of multilingual IE), Gamallo and Garcia (2015).

Search and Knowledge Graphs

The kind of structured querying described in this article is more broadly known in the literature as *entity-centric search*, defined by Dalvi et al. (2009) as creating a ‘semantically rich aggregate view’ of concept instances on the Web. Entity-centric search has led to novel insights about the search process itself, two examples being knowledge base acceleration and filtering (Frank et al., 2012), and interactive search and visualization as in the Timemachine system (Saleiro, Teixeira, Soares & Oliveira, 2016). More recent work on entity-centric search includes the work by Kejriwal and Szekely (2017b), Querytogether (Andolina et al., 2018), Deeplife (Ernst et al., 2016) and InfoScout (McKeown et al., 2016). The

patents filed by Pantel et al. (2017) and Roberts et al. (2016) are also relevant, especially for insights in the industrial space.

While interactive search and visualization is particularly relevant to the present work, many established search systems are designed to keyword-only queries rather than for the kinds of aggregation and dossier generation queries (subsequently described) that are so fundamental for robust DSS. This also distinguishes the concepts described in this article from other similar research that fuses Semantic Web research with IR research on tasks such as ad-hoc object retrieval (Freitas et al., 2012; Tonon, Demartini & Cudre-Mauroux, 2012). Despite the differences, important elements of the DSS described herein are inspired by the hybrid (instead of purely structured or unstructured) search techniques used for entity-centric search tasks in these systems.

In more recent years, entity-centric search has been used in commercial search engines like Google. For example, keyword searches like ‘Albert Einstein’ are now treated by Google both as keyword and as entity-centric search. For facilitating the latter, Google uses its underlying Google Knowledge Graph technology, based on a proprietary version of the (previously open-source) Freebase knowledge base (Bollacker et al., 2008; Singhal, 2012). However, the query medium is still largely keyword based, unlike the complex queries that illicit-domain DSS systems can handle. Another extremely important difference is that illicit domains like human trafficking exhibit a *long-tail* distribution (Kejriwal & Szekely, 2017b) that is uncharacteristic of entities in the Google Knowledge Graph, which largely contains world knowledge from a handful of sources such as Wikipedia and Wordnet (Gabrilovich & Markovitch, 2007; Miller, 1995). More recently, schema.org and markups have started to play an important role in populating the Google Knowledge Graph (Paulheim, 2017; Nam & Kejriwal, 2018).

Human Trafficking

One of the most important aspects of this article is its focus on a non-traditional domain that has an outsize presence on the Web, and by some estimates is a multi-billion dollar industry, but due to technical and social reasons, has largely been ignored by the computational, knowledge management and IR research communities till quite recently (Hultgren, Jennex, Persano & Ornatowski, 2016; Alviri, Shakarian & Snyder, 2016). An exception, and a prime focus of this article, is the DIG (Domain Insight Graphs) system. Similar to the DeepDive system (Niu et al., 2012), which also makes knowledge graph construction intuitive, DIG implements KGC components, includes a GUI, and was evaluated on human trafficking data (Kejriwal & Szekely, 2017b).

More broadly, semi-supervised and minimally supervised AI has been applied to fight human trafficking in contexts beyond information extraction and search (Kejriwal et al., 2013; Rabbany, Bayani & Dubrawski, 2018; Alviri, Shakarian & Snyder, 2017; Burbano & Hernandez-Alvarez, 2017). As one example, the FlagIt system (Kejriwal et al., 2013) attempts to semi-automatically mine *indicators* of human trafficking, including movement, advertisement of multiple girls etc. As another example, Rabbany et al. (2018) explore methods for active search of connections in order to build cases and combat human trafficking. Finally, although this article deals primarily with linguistic data (since it is focused on IE, which tends to work on linguistic data), there has also been a steady stream of work on the non-linguistic characteristics of sex ads. For example, recently, Whitney et al. (2018) describe how emojis can be used to add a layer of obfuscation to sex ads to avoid getting investigated, caught and prosecuted. Even if investigators invested the effort to painstakingly construct ground-truths, the creative and dynamic ways in which traffickers adapt (e.g., by using obfuscations such as emojis and misspellings)

would soon render those ground-truths stale and obsolete. Hence, there is a real need for developing end-to-end unsupervised IE systems, both for acquiring and evaluating extractions.

Finally, although this article is mainly concerned with building DSS engines for human trafficking, we believe that the core findings apply to other illicit domains e.g., from the Dark Web (Chen, 2011), that are highly heterogeneous, dynamic and prone to deliberately obfuscate key information like phones (Table 1).

FOCUS OF THE ARTICLE

This section introduces the problem of domain-specific search (DSS), especially in the context of fighting illicit activity (sex advertising activity is used as the primary example) with an online footprint, and the challenges that successful DSS must overcome to adequately solve this problem. Solutions and recommendations will be described in the next section.

The field of online search, as it exists today, has been largely researched under the banner of information retrieval (IR). The majority of IR research has tended to focus on generic search and generic users, embodied by search engines like Google and Bing. According to Yan, Song and Li (2006), domain-specific IR has become more popular in the last decade since ‘not only domain experts, but also average (i.e. non-expert) users are interested in searching domain specific information from online resources’. Although their work was primarily in the health and medical area, and the IR they are referring to is still *document-centric*, the key motivation (making such technology accessible to non-experts) has become ever more important in an age when machine learning and other models have become complicated to set up. In illicit domains, where the primary users are law enforcement and people who do their investigative work ‘on the ground’, it is ever more important to make domain-specific search technology accessible, relatively complete and trustworthy, and easy to use.

Furthermore, one could reasonably argue that, the more complex the domain, the more sophisticated the needed IR facilities. To distinguish the traditional definition of ‘domain-specific IR’, which has involved corpora of domain-specific definitions, this article refers to the problem of satisfying investigators’ needs in a domain such as online sex commerce as domain-specific *search*. In the context of this article, domain-specific IR involves a subset of DSS. In the simplest case, an investigator could enter a search lead, such as a phone number, or some keywords (e.g., describing the physical attributes or last known location of a victim), and expect an IR-like solution where a *ranked* list of relevant advertisements (hopefully containing not just the keyword query but also additional details that the investigator can use to search *further*) appear. The utility of such *point fact* queries¹, while necessary, is hardly sufficient. Generally, investigators want more detailed information, including aggregations. For example, the investigator may want to enter the phone number and expect the system to *know* that the number is a phone number, and show her *all available* information (a ‘dossier’ capturing global information) on that phone number (including activity timelines, counts of ads the phone has appeared in, associated email addresses etc.). In other words, the system should not only have some notion of *semantics*, but should be capable of *global* rather than *local* processing of retrieved answers. We provide examples of some of these query types from the HT domain in Table 2.

In fact, a truly robust DSS system should be able to accept hybrid questions that are a combination of point fact, aggregation and the *dossier generation* query mentioned above informally. An example of such a question from the human trafficking domain is *Return a time series of activities of phone numbers associated with the following information set: Name: Candie, Location: Los Angeles, Services Adver-*

Table 2. Real-world examples of the different structured question categories in the human trafficking domain (identifying information has been masked). Many of these query categories have also been found to apply to investigative IR tasks in other illicit domains, including penny stock fraud.

Query category	Example
Point fact	Find names of escorts associated with phone number 123-456-9999 who are older than 23
Cluster identification	List all ads connected via a shared email address to the email XXX@Z.org
Cluster facet	List all ads connected via a shared phone number or email to the phone number 1234400 that optionally feature the phrase ‘Maria funsize’ in the description
Cluster aggregate	Find most common ethnicity of escorts associated directly with phone number 123-456-9999

tised: *Massage, Nuru*. The point fact aspect of the query arises from the information set specified, while aggregation is required because the user has asked for all phone numbers associated with the information set. Finally, the activity time series of each of these phone numbers can only be obtained from the dossier compiled on that phone number.

Note that, for higher accuracy, the user would actually specify such questions using *forms* or structured queries so that user intent is not misinterpreted by the system. Figure 2 illustrates the query interface for the DIG DSS instantiated for the human trafficking domain with some fields filled in. The query is now not just a ‘bag of words’ but contains words with semantics (since they are specified for fields like Product and Email) and can be further enriched using disjunctions (by using comma between terms) and conjunctions (by clicking on the star symbol next to the field so that it turns from blue to yellow).

The query that emerges as a result of such inputs is reminiscent of an SQL or SPARQL query prevalent in the database (and for SPARQL, Semantic Web) community. Even there, one must be careful. Executing the query ‘as is’ is often problematic because of the *noise* in AI modules (like information extraction; see also the challenges subsequently enumerated) alluded to in the introduction. For example,

Figure 2. The DIG DSS search form (‘query interface’) for the human trafficking domain that allows users to pose semantically-enriched queries

considering the query above, there may be some ads where Candie's location is 'LA' rather than 'Los Angeles'. In other ads, Candie's name may be misspelled, but the rest of the context in the ad may still make it evident that the person is the same. To handle such cases, *query reformulation* is required. That is, the constraints and inputs in the original query must be modified to 'capture' such cases without introducing too much noise, so that aggregation and dossier generation results are not overly conservative.

Building DSSs that can generalize in the ways described above, in illicit domains, is a challenging problem, especially with limited resources. Table 3 briefly lists and describes some of these challenges. In normal cases, to maintain good quality and coverage, an investigative customer would have no choice but to hire a technical team to understand their needs and construct a DSS over months or years of effort. This is out of reach for resource-strapped investigative agencies in most countries. The DARPA Memex program, mentioned earlier, was a 4-year program that attempted to democratize the *construction* and *use* of powerful DSS technology by non-technical investigators². Use of such engines, once constructed, could be accomplished through an intuitive Graphical User Interface (GUI) and some training, but construction required creativity, since it is traditionally the domain of technical experts. The technologies and architecture that resulted from years of research on Memex are described in the next section.

SOLUTIONS AND RECOMMENDATIONS

Given the problem definition of DSS as described in the previous section, and the numerous, formidable challenges that successful DSS must overcome, what should a good solution 'look' like? This section describes an *architectural* solution that has been instantiated and developed over the course of the DARPA Memex program and transitioned to, and tried by, multiple law enforcement agencies in the United States

Table 3. A non-exhaustive set of challenges that an illicit-domain DSS must generally overcome to be useful to real-world investigators

Heterogeneity of webpage structure , making wrapper induction difficult to automate with sufficient quality. In the human trafficking domain, many sex ad portals have to be crawled, which makes generalization and manual training too infeasible
Non-traditional nature of domain, including linguistic patterns (see Table 1 for examples from the human trafficking domain) and types of fields in the domain ontology; e.g., uncommon fields like stock ticker symbols have to be extracted for the penny stock fraud domain, while physical attributes, phones, locations and sex services provided have to be extracted for HT
Scale and infrastructure , since a truly comprehensive DSS must involve sophisticated query execution over domain-specific corpora crawled at Web-scale
Robustness to potentially irrelevant content both in the corpus and within webpages; for example, in the human trafficking domain, webpages on backpage.com and other portals often feature sponsored ads that can be difficult to automatically ignore
Presence of missing values and noise , due to both information obfuscation (see below) and due to imperfection in the AI systems for extracting key attributes; e.g., due to creative writing of phone numbers in the human trafficking domain, and conflation with other numeric attributes like age (last row of Table 1)
Robustness to information obfuscation , since illicit players are often trying to evade investigative search by creatively masking identifying information (examples from the human trafficking domain of both obfuscated phones and names are shown in Table 1)
Complex query types , since, as Table 2 described for the human trafficking domain, domain-specific search for investigative IR involves operations like aggregation and dossier generation, in addition to the point-fact style queries of traditional IR engines
Preclusion of live Web search , due to the dynamic nature of illicit domains where webpages are frequently taken down and possibly 're-posted', sometimes with different pictures and locations. To answer questions involving time series, for example, pages have to be <i>cached</i> , which makes scale even more of a challenge. In the human trafficking domain, such pages have also been used for evidence gathering (as the Memex tools have been used in various documented prosecutions).

to fight human trafficking. While covering the full technical breadth of the solution is beyond the scope of this article, key details and design decisions are described, with pointers to further reading.

The architectural overview of the DSS developed under Memex is illustrated in Figure 3. As a first step, the system attempts to discover relevant websites in the user's *domain of intent* through a process that goes alternately by the name of *domain discovery* or *intelligent crawling*. In the literature, the latter term is more prevalent, having been researched under various settings (Aggarwal, Al-Garawi & Yu, 2001), but more recently, the former term has also started becoming popular (Krishnamurthy, Pham, Santos & Freire, 2016). The idea is to (iteratively) accept as input, various intuitive cues describing the domain such as keywords and websites, and find *relevant* webpages on the Open Web that seem to conform to the definition of the domain. For example, in the human trafficking domain, seed keywords would include terms such as 'escort' and 'massage parlor' and a seed website might be 'backpage.com'. Concerning relevance determinations, one could use classic techniques (such as a pre-trained learning-to-rank classifier) but over the course of the Memex program, methods employing reinforcement learning and lower-supervision machine learning paradigms have also been explored with success. A good example of a system implementing many of these techniques and also offering an intuitive interface to the user who is attempting to provide seeds and define the domain, is ACHE, developed by a group at New York University (Krishnamurthy et al., 2016).

The second step, which is much more challenging and can determine the quality (especially, *precision*) of the system and its outputs as a whole, is *knowledge graph construction (KGC)*. KGC encompasses a set of roughly sequential techniques (see Background for related work and references), such as information extraction, entity resolution and advanced knowledge graph identification techniques such as knowledge graph embeddings. All of these techniques are designed to operate in tandem to ingest a corpus of raw data (usually, natural language documents or 'semi-structured' webpages) as input and to output a *knowledge graph (KG)*, which is defined as a directed, labeled multi-relational graph expressing entities (labeled nodes) and relationships between entities (labeled edges).

Among these steps, Information Extraction (IE) is a well-studied area in both the natural language processing and Web communities (Chang et al., 2006). Except for the problem of *Open IE*, almost all

Figure 3. An architectural overview of the DSS developed under the DARPA Memex program, particularly for human trafficking

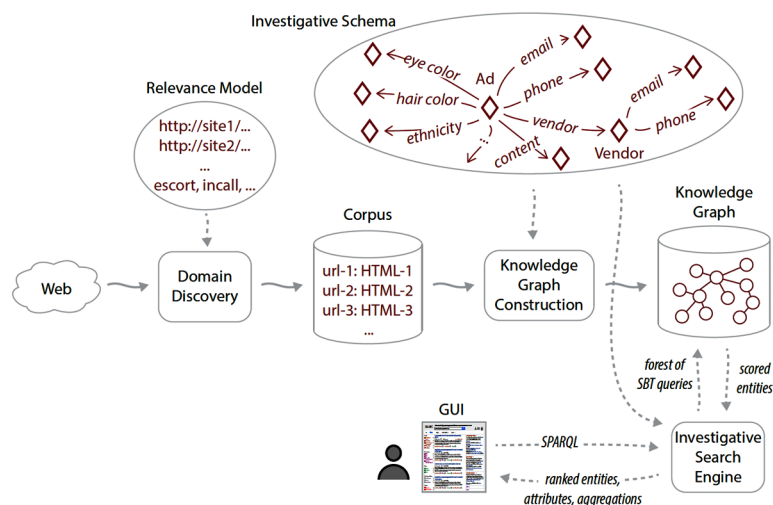

Figure 4. A brief illustration of knowledge graph construction (KGC) wherein relevant attributes (specified according to a domain-specific investigative schema) are semi-automatically extracted and resolved into a directed, labeled multi-relational KG

other forms of IE are *ontology-based*. That is, an underlying ontology, which could be as simple as a set of terms (e.g., PERSON, LOCATION and ORGANIZATION) or a complex event ontology such as ACE, which ontologizes events ranging from interaction to movement and destruction, including attacks (Doddington et al., 2004). In the case of illicit domains, the ontology in terms of which IE is performed is referred to as an *investigative schema*. A real fragment of the investigative schema developed by experts for investigating human trafficking is shown at the top of Figure 3, and includes both physical attributes, as well as identifying attributes such as phone number.

Following IE, steps such as Entity Resolution (ER) can be undertaken to clean up the KG even further (Getoor & Machanavajjhala, 2012). Again, in illicit domains, one should always attempt to customize the ER algorithm to achieve higher performance. For example, phones tend to be highly obfuscated in sex advertisements, making it likely that phone extractions have noise that obeys certain characteristics (e.g., extra digits, presence of the + symbol or extra 0s etc.). ER can be customized to take these cues into account to achieve higher precision or recall. Other advanced techniques like knowledge graph embeddings are also applicable. The reader is referred to a survey on knowledge graph refinement for full details on these procedures (Paulheim, 2017).

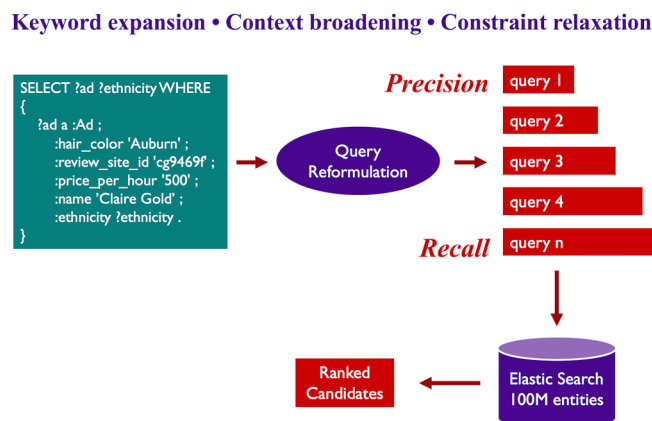

Ultimately, the end result of knowledge graph construction (and optionally, but recommended, refinement) is a knowledge graph. This knowledge graph can be queried in a structured language, using intuitive interfaces like forms, options and even free-text. However, the KG will be noisy, despite application of advanced KGC and refinement, and the query may not always fully express user intent. Thus, query reformulation is an important recommended step that must be used for good performance. In experiments conducted under the Memex program, even simple query reformulation was found to be necessary to achieve non-zero performance on query retrieval metrics like Mean Reciprocal Rank (Kejriwal & Szekely, 2017b).

The original query, which would usually be expressed using a form such as in Figure 2, is (approximately) rendered in SPARQL. The strength of a reformulated query's weight is generally inversely related to the amount of reformulation compared to the original query. The query is from the HT domain.

An intuitive visual description of query reformulation is given in Figure 5. As the figure shows, a query can be reformulated using a variety of well-researched techniques (keyword expansion, constraint relaxation and context broadening) designed to expand the coverage of the query. The simplest of these techniques is keyword expansion, which involves *supplementing* the original words with *related* words to help improve search recall. As an intuitive example of keyword expansion, one could replace an instance of a 'sub-type' ethnicity like 'Japanese' with a super-type ethnicity like 'Asian', or a color like 'auburn' with the synonym 'red'. Another example technique is constraint relaxation, which involves turning some of the query specifications into *optionals* so that not every criterion has to be successfully met for a result to be retrieved. This can especially help with misspellings, difficult-to-extract attributes or unusual synonyms.

In practice, the more aggressive query reformulation is, the more precision can suffer. This may help the system to retrieve some more relevant results, but it will also bring irrelevant ads into the fold. Similarly, instead of looking for 'Japanese' in the ethnicity field, the query could be relaxed to search against the entire text. This improves recall but can also backfire. The trick is to leverage the global power of the system by compiling the final set of results through combining individual query results. NoSQL retrieval systems like Elasticsearch, on which the DIG backend is based, make this easier on the engineering front by accepting multiple weighted queries as input as a *forest* of queries, and producing a final set of ranked results through combining and re-ranking. This final set of results is then displayed to the user. By leveraging advances in IR, including advanced indexing methods, results can be retrieved quickly.

Figure 5. An illustration of query reformulation

One aspect of an illicit domain DSS that should never be underestimated is the design of the Graphical User Interface (GUI) that the non-technical user uses to access the system. The backend of the system, including the actual query posed against Elasticsearch, should be insulated from such users. However, the user should still be given control both over KGC and over the search itself. Considerable research and user testing was conducted on systems like DIG to ensure that users were equipped to handle and remember system functionalities. In the case of KGC, users were shown how to define their investigative schema and declare meta-attributes like the importance of fields, whether the field should be visible to search against, the data type (e.g., numeric vs. string) of the field etc. Users were also able to handle expressive search facilities, including when to declare a specification as optional. A visualization of the search form was earlier shown in Figure 2.

FUTURE RESEARCH DIRECTIONS

Despite enormous progress under the DARPA Memex program and several others before it, domain-specific search (DSS) continues to be an important problem that is amenable to interesting exploration. One action item that the community should adopt is to assess the adoption of the technology described herein to illicit domains other than human trafficking (HT). Several promising domains for which DSS feasibility and pilot implementations have already been explored (but not significantly expanded, as in the case of HT) are enumerated below:

- **Counterfeit Electronics Sales:** Despite what the name suggests, investigators in the counterfeit electronics domain are interested, not in consumer electronics, but in microchips and field-programmable gate arrays (FPGAs) that form the computational backbones of more complex devices. The FPGAs may resemble an FPGA from a genuine contractor, but are fakes, and may have malicious modifications at the hardware level. Certain countries, companies and devices are more relevant to this kind of activity than others. Note that there is an obvious national security component to these investigations, and just like with the other described domains, domain expertise plays a crucial role both in setting up the domain, and in the knowledge discovery itself. The ability of a DSS to be set up on private infrastructure or premises is especially important in matters of national security, though generally, the requirement emerges an important one in almost every domain of an investigative nature.
- **Mail Shipment Fraud:** Illicit shipments via USPS happen in the physical world but *communications* about the illicit shipment, particularly tracking numbers, happen *digitally* in specific forums and typologies that investigators in this domain understand well. DSS can help investigators find and crawl information across multiple sources (domain discovery) and then aggregate and compartmentalize this information according to specific investigative needs.
- **Securities Fraud:** Securities, particularly *penny stock*, fraud is a complex and unusual domain because much of the activity that accompanies fraudulent behavior, including hype and promotional activity, is legally permitted. Many of the actual actors involved may not be physically present in the US, but for regulatory reasons, ‘shell’ companies fronting such activity for promotional and legal purposes, have to be registered in the US to trade stocks legitimately in over-the-counter exchanges. In addition to the longer-term goal of investigating, and gathering information on, such shell companies and the people involved in them, investigators are also interested in taking preventive activity. This can happen when a penny stock company is caught actively engaging in

factually (i.e. provable) fraudulent hype (for example, a false claim that a contract was just signed with a well-known customer firm), in which case trading can be halted or even shut down. DSS can support these investigate and preventive goals by allowing users to aggregate information about suspicious penny stocks crawled over the Web, zero in on burgeoning promotional activity and compile dossiers to discern patterns between multiple stocks.

- **Illegal Firearms Sales:** In the US, firearms sales are regulated in that transactions cannot be conducted over arbitrary channels like the Internet. Investigators in this domain are interested in pinpointing activity that, either directly or indirectly, provides evidence for illicit online sales of firearms that leave some digital trace. The domain is similar to the securities fraud domain (and dissimilar to the counterfeit electronics sales domain) for the important reason that investigators tend to limit their focus to *domestic* activities.

CONCLUSION

This article explored the problem of domain-specific search (DSS) for illicit domains that have exploited the Web to gain increased market share. The human trafficking domain, where this problem has been most explored, was used as a clarifying example both in terms of the challenges and recommendations involved. Although much progress has been made, and the solutions described in this article have been adopted into real systems that have been used by law enforcement for convicting traffickers, much work still remains to be done. In particular, the findings need to be extended and tested on other illicit domains. The scope of the DSS can also be significantly expanded. One avenue for future exploration is to enable natural language question answering and conversational interfaces so that investigators can access the system even more intuitively. Finally, as existing AI technology for information extraction and knowledge graph construction continue to improve, an engineering challenge is to ‘roll out’ updates to different modules in a way that does not have unexpected negative consequences on the system’s behavior. This is a general challenge with composing and using multiple AI technologies, and DSS is no different.

KEY TERMS AND DEFINITIONS

Domain-Specific Search (DSS): The problem of building a (rudimentary or advanced) search engine over a domain-specific corpus. Domains of special interest in this article were illicit domains such as human trafficking, over which building such an engine is an especially challenging problem.

Entity Resolution: Entity resolution (ER) is the problem of algorithmically determining when two entities in a KG refer to the same underlying entity. For example, the same entity ‘Barack Obama’ may have been independently extracted from two webpages under names such as ‘President Obama’ and ‘Obama’.

Information Extraction (IE): Information extraction (IE) is an algorithmic technique that generally accepts as input either text or raw HTML as input, and outputs a set of ontologically typed instances. For illicit domains, the investigative schema serves as the ontology. Supervised machine learning and deep learning IE methods have emerged as state-of-the-art in recent times.

Investigative Schema: An investigative schema is an ontology expressing an investigative domain of interest, usually involving an illicit activity like sex advertising. The investigative schema is usually simple and shallow, hence the term ‘schema’ and not ‘ontology’.

Knowledge Graph (KG): A knowledge graph (KG) is a directed, labeled multi-relational graph that is used to model and represent semi-structured data to make it more amenable to machine reasoning (‘knowledge’).

Ontology: An ontology may be practically defined as a controlled set of terms and constraints for expressing the domain of interest. An ontology can range from a simple set of terms (e.g., {PERSON, LOCATION, ORGANIZATION}) to a taxonomy (with concepts and sub-concepts e.g., ACTOR and ENTREPRENEUR would be sub-concepts of PERSON) to a general graph with equational constraints e.g., that the domain and range of the relation *starred-in* is ACTOR and MOVIE respectively. Any KG that is ontologized thus should obey such constraints at the instance level.

Query Reformulation: Query reformulation refers to a set of techniques wherein a query (in some domain-specific language like SPARQL or SQL) that is originally posed against a DSS engine is reformulated into a set of queries (in the same or different language) to increase query retrieval performance. Query reformulation is a useful technique both when the underlying KG is noisy and when the original query does not fully express (or over-conditions) user intent.

ENDNOTES

- ¹ This terminology is non-traditional and was set by DARPA and NIST over the course of the DARPA Memex evaluations.
- ² A general description of the Memex program can be accessed at <https://www.darpa.mil/program/memex>. Domain-specific search technology developed under Memex can be used for constructing and using DSS engines not just for illicit domains, but also non-illicit domains. Many of the tools have been released as open source under permissive licenses.

Identifying Victims of Human Sex Trafficking in Online Ads

INTRODUCTION

Trafficking humans for sexual exploitation is a fast-growing criminal enterprise even though international law and the laws of 158 countries criminalize sex trafficking (Equality Now, 2017). The Equality Now (2017) *Sex Trafficking Fact Sheet* lists these statistics:

- Sex trafficking is a lucrative industry that makes an estimated US\$99 billion a year.
- About two million children are exploited every year in the global commercial sex trade.
- Women and girls make up 96 percent of victims of trafficking for sexual exploitation.

Further, human trafficking is not just a third or developing world problem. The National Human Trafficking Resource Center hotline lists 5784 human sex trafficking cases reported in the United States during 2016 (NHTRC, 2018a). Additionally, the National Human Trafficking Resource Center has reported that California had 1050 of these cases (NHTRC, 2018). (Note that this chapter and research uses a sample set from California, United States and so statistics, policies, and laws used in this chapter are focused on this region)

The U.S. Government defines human trafficking as inducing others to perform a commercial sex act by force, fraud, or coercion; as inducing a person under 18 years of age for such an act; and/or as recruiting, harboring, transporting, providing, obtaining a person for labor or services through the use of force, fraud, or coercion in order to subject them to involuntary servitude, peonage, debt bondage, or slavery (National Institute of Justice, 2012). However, the Department of Homeland Security (DHS) has more recently shortened the definition of human trafficking to a contemporary form of slavery that

DOI: 10.4018/978-1-5225-9715-5.ch034

involves the illegal trade of people for exploitation or commercial gain (Department of Homeland Security, 2014). Further clarifying this definition, California's Department of Justice (DOJ) has stated that human trafficking is a contemporary form of slavery that involves controlling a person through force, fraud, or coercion to exploit the victim for forced labor, sexual exploitation, or both (Harris, 2012). While slightly different, all three definitions are similar in context. However, for this paper, we use California's DOJ's definition but note that two classes of human sex trafficking exist: those for victims under 18 (minors) and those for 18 or over.

In this paper, we focus on the sex trafficking aspect of human trafficking and propose an information systems approach to identify sex trafficking victims based on analyzing online (Internet) ads. We focus on online ads because social media and the interactive Web have enabled traffickers to lure victims and sell them at a faster rate and in greater safety than ever before. However, these same tools have also created new avenues for prosecution and criminal investigations for law enforcement as officials now have access to a vast amount of information about the sex industry. We use system development methodology from action research (Nunamaker, Chen, & Purdin, 1990; Burstein & Gregor, 1999) with a knowledge management strategy approach of identifying actionable intelligence (i.e., identifying victims of human sex trafficking) by applying a set of strong filters based on an ontology of keywords that codifies attributes of human sex trafficking victims to assess an unstructured dataset consisting of the text from online ads scraped from the women looking for men section of backpage.com.

Specifically, we address the following research question:

RQ: Can one use online data to identify victims of human sex trafficking?

To answer this question, we created a prototype to explore text-based indicators of human trafficking in online classified ads (see section 4.1 for a list of these terms). In particular, we created the prototype to:

- Create an ontology/keyword list of terms and/or attributes that may indicate human trafficking
- Create a process for extracting an unstructured text dataset from online advertising, and
- Use the keyword ontology to construct strong filters that can be applied to the unstructured dataset to determine ads that create actionable intelligence on identifying victims of human sex trafficking.

Additionally, during the study of keywords in online ads we discovered that emojis were being used in lieu of keywords leading to the addition of the following purpose for the final prototype (see section 5.2.2 for the emojis identified as being used in human sex trafficking):

- Add emojis to the keyword ontology and use them to construct strong filters that can be applied to the unstructured dataset to determine ads that create actionable intelligence on identifying victims of human sex trafficking.

The prototype we created utilized: Strong filters that combined knowledge/experience-driven ontologies of keywords and emojis that modeled human sex trafficking victims

- A process for updating the ontology
- A process for extracting an unstructured dataset of online ads, and
- A process for analyzing the unstructured dataset using evaluation criteria for determining what ads are actionable

Technologies in the prototype included ontologies, machine learning, text mining, and Web scrapers.

KNOWLEDGE MANAGEMENT, TECHNOLOGIES, AND TRAFFICKING INDICATORS

3

Knowledge Management

We used a knowledge management, KM, approach to develop and apply ontologies (defined later) to create strong filters to help identify potential victims of human sex trafficking in online advertising. In this section, we review the literature and theoretical base for using knowledge management to help develop a system implementation to assist in searching for human sex trafficking victims.

Jennex (2005) defines KM as the practice of selectively applying knowledge from previous decision making experiences to current and future decision making activities to improve an organization's effectiveness. Jennex (2017) incorporates big data and the Internet of things (IoT) (see Figure 1 below) into Jennex and Bartczak's (2013) modified knowledge pyramid and uses the final revised pyramid to define the purpose of KM as identifying, generating, capturing, and using actionable intelligence. Actionable intelligence is that knowledge that can be directly and immediately applied to make a decision. KM processes filter IoT, big data, data, information, and knowledge to generate specific, actionable intelligence that the organization can share with specific, limited users. Additionally, Jennex (2017) places filters on social networks to limit access and to separate and capture that which the organization needs from that which it does not. In this vein, "filters" is a fairly new term for KM, and we view KM filters as the implementation of KM strategy. While KM requires all the components in the figure and we use them all in this research, we consider KM strategy and KM content the most important in designing and implementing the prototype that we present in this paper. KM strategy determined needed actionable intelligence, guided us in determining what data and information to collect, and finally guided us in designing and constructing the filters.

Filters were designed using ontologies. Ontologies codify knowledge by providing a simplified and explicit specification of a phenomenon that one desires to represent (Gruber, 1995; Noy and McGuinness, 2001; Staab, et al., 2001). Ontologies are useful because they explicate components that define a phenomenon and, thus, can help in systematically understanding or modeling that phenomenon (Holsapple & Joshi, 2004). Keywords/terms are specific examples from an ontology with a complete set of keywords/terms that define an ontology. Alavi and Leidner (2001, p. 114) define a KMS as "IT (Information Technology) based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application". Many researchers include ontologies in the KMS as tools for organizing and retrieving knowledge (Aldea et al., 2003; Almeida & Barbosa, 2009; Holsapple & Joshi, 2004; Jurisica, Mylopoulos, & Yu, 1999; Varma, 2007; Wu & Yang, 2005).

We created ontologies by identifying keywords from the experience literature that describes the phenomenon of human sex trafficking. We then used our first ontology in a KMS that applied the ontology to a set of unstructured ad data to create actionable intelligence that we could use to identify potential victims of human sex trafficking in online advertising. Subsequently, we created a new ontology based on more current literature and a second dataset and then used machine learning tools to enhance this ontology based on patterns in the ad dataset and applied the enhanced ontology to identify potential victims of human sex trafficking in the second dataset. In the future, we plan to use machine learning tools to automatically generate an ontology from a new dataset.

Technologies for Combatting Trafficking

Amin (2010) discusses the potential benefits of using machine learning as a tool to combat human trafficking. These benefits include; detecting features and unusual patterns indicative of potential cases of human trafficking, identifying rules that can assist in predicting trafficking activity and profiling victims and criminals, and help in automating pattern identification and search process for potential instances of trafficking online. One application of machine learning techniques for combatting online sex trafficking involved the use of a sample of backpage.com ads from March 2016 to train a learning classifier. The ads collected from backpage.com were first filtered using known indicators of online sex trafficking and feature engineering. The six categories used for creating the feature set included; ad language pattern, words and phrases of interest, countries of interest, ad of multiple victims, weight of victim, and whether the ad reference an external website or spa massage therapy. Following this unsupervised filtering, a small portion of the remaining ads were then labeled by human experts as to whether they were instances of human sex trafficking. A semi supervised learning algorithm was then used to label the remaining ads and the classifications were then reviewed by experts in online sex trafficking to evaluate accuracy. Radial basis function (92.41% True Positive Rate) and K-nearest neighbor (90.42% True Positive Rate) kernels were used to assign classifications and both learning models were able to predict online instances of sex trafficking with high accuracy (Alvari, Shakarian, and Snyder, 2016). This study indicates the high potential of using machine learning techniques to identify ads that are potentially human trafficking related. Additionally, the use of semi-supervised methods makes the modeling technique more realistic for real world application because obtaining large enough samples of labeled data for a purely supervised learning algorithm is not very plausible.

Dubrawski, et al. (2015) trained multiple random forest models using three differed information extraction approaches, term-frequency analysis using law enforcement provided keywords, regular expressions, and natural language processing. Of these three, the natural language processing feature set

Figure 1. The final revised knowledge pyramid

Source: Jennex, 2017

had the highest accuracy in predicting actual instances of human sex trafficking, lowest false positive rate, followed by the keyword feature extraction method. The natural language processing feature set was obtained by compiling a bag of words from online escort ads and then using principle component analysis for dimensionality reduction (Dubraski, et al., 2015).

Research on the use of machine learning techniques to combat child sex trafficking has also involved the architectural design and prototyping of Traffic Bot and WAT – Web Archival Tool, its successor. Traffic Bot crawls websites known for ad postings for escort and massages services to collect data and then provides an interface to drill down the collected ad data based on phone numbers as a tool to identify potential cases of sex trafficking. Wang, et al. (2014) in designing the Traffic Bot framework examined how classified escort ads disguise phone numbers with the use of unusual punctuation and spelling and character or word substitution. They identified a regular expression method to be effective in detecting and decoding these phone numbers and used this technique as their filtering method. They were able to detect ads where the same phone number was listed for different women or multi-person services, two indicators of potential trafficking. They also note that by using the interface to drill down by phone number and identify instances where the area code differed from the location of the ad posting, one may be able to identify the location of a home base (Wang, et al., 2014). WAT – Web Archival Tool was geared specifically at identifying underage victims of sex trafficking (Hovy, et al., 2014). Hovy et al. (2014) clustered data collected via a daily web crawler of websites advertising escort services based on relationships between the postings themselves or poster of the ad. The system facilitated dynamic cluster movement as new data was added and provide three interfaces with which to analyze the resulting clusters (Hovy, et al., 2014).

These technologies are used to enhance KM and fit into KM/KMS as shown in Figure 1. Figure 1 shows that these technologies are used to construct filters that are used to convert data to information, knowledge, and actionable intelligence. Additionally, these filters assist users in generating sense making from the data, information, knowledge and actionable intelligence.

Indicators of Sex Trafficking in Ads

We reviewed the literature for research that focused on identifying victims of sex trafficking through indicators found in ads. We reviewed these indicators for those that we could operationalize through a set of key words/ontology. The below list and literature reflects those indicators that met this requirement.

Movement Between Cities

Ads that evidence frequent movement, or transience, may signal that a sex worker is a victim of trafficking. Pimps often move victims around from city to city in order to avoid law enforcement and to maintain control by keeping victims from building a social support system or becoming too familiar with a particular area (Dank et al., 2014). This movement also keeps victims disoriented and ignorant of where to seek help (Harris, 2012). However, pimps tend to move victims in groups or stables. Ultimately, this steady movement leaves women and girls consistently vulnerable to those who control them. Indeed, a study on trafficking in Silicon Valley found that traffickers often move sex workers around the Bay Area (Juniper Networks, 2014). The frequent movement between cities also has a marketing side. It serves to maintain a “fresh” product line for clients (Harris, 2012). In this way, traffickers constantly circulate “new product” to entice consumers (Ibanez & Suthers, 2014). They often move international women from the East to the West Coast, South to Northeast, and from urban to rural and vice versa. American

women are trafficked across city and state borders and internationally (Raymond, Hughes, & Gomez, 2001). Additionally, traffickers may post ads in other cities to gauge the market in that area based on the amount of hits they get (Dank et al., 2014). By analyzing phone numbers posted in ads, researchers can identify area code networks in online escort service ads that can further identify patterns of victim movement in a geographical area (Ibanez and Suthers, 2014).

Ethnicity and National Origin

Ibanez and Suthers (2014) reference the denotation of ethnicity as a possible sign of trafficking. One needs to use this indicator in context of the dataset one analyzes before including it as an indicator to ensure that the dataset uses a variety of ethnicities/national origins because an estimated 72 percent of sex trafficking victims in California are American citizens. Thus, being “American” is not effective as an ethnicity or national origin term for identifying a potential trafficking victim.

Restricted Movement

Law enforcement officials believe that pimps consider it safer to conduct activities online and use incalls only (Dank et al., 2014). Previous studies have used restricted movement seen through terms such as “incalls only” as a possible indicator of sex trafficking (Ibanez & Suthers, 2014). To control their victims, perpetrators often deny them their freedom of movement and keep them isolated.

Unconventional Sex

One ad that researchers found to advertise a victim of sex trafficking included the term “open minded” (Operation Broken Silence, 2012), which may be a code word that signifies that customers can perform unconventional and sadistic types of sex. As such, an ad with such a phrase may increase the likelihood that the sex worker it advertises is a victim of trafficking (Yen, 2008).

Minors Trafficked Online

Sellers solicit buyers who are interested in purchasing young girls (often minors) using certain keywords that can indicate a sex trafficking victim. Ads for underage victims sometimes use words such as: fresh, fresh meat, young, virgin, prime, coochie (shaved), non-pro, new, new in town, barely legal/18, college student/girl, lovely, daddy’s little girl, sweet, 1986 Firebird, new in the life, liked girls, youthful, and fantasy (Bouche, 2015; Boyd, Casteel, Thakor, & Johnson, 2011; Major, 2012).

Phone Numbers and Area Codes

Classified ads often include phone numbers. Customers and sellers sometimes use them to look up reviews on a particular girl and to see if the girl has alternate names (Ibanez & Suthers, 2014). Traffickers and victims often use multiple (both contract and disposable) phones in sex trafficking operations. Latonero et al. (2012) looked at the distribution of phone numbers using a simple Google search and found the phone number of one suspected victim on seven other escort service websites for multiple cities. Additionally, they found the same phone number on MyRedBook with a different name but similar photographs. This widespread advertisement across the Internet and geographic regions indicates

more than just alone prostitute out to make extra money. It could even indicate a sex trafficking ring. Information from area codes strongly indicates the movement of victims and traffickers. The area code network offers both a source and destination. One can generate maps to determine suspected routes that sex traffickers use to transport victims from one location to another.

METHODOLOGY

System Development Method

We used the systems development research methodology from action research that Nunnemaker et al. (1990) and Burstein and Gregor (1999) describe. We chose this methodology in order to produce a system that combines technology with social understanding for detecting ads that offer the services of victims of human sex trafficking. Systems development research methodology is a multimethodological conceptual approach that incorporates theory building, experimentation, and observation into systems building. System building is a form of applied research that focuses on solving a specific problem. Further, the system development method theory uses observation, and experimentation (or prototyping) methodologies to create the system. The system development method has five basic steps:

1. Identify and/or generate theory applicable to solving an information system (IS) problem. The system development method does not need to create this theory, but one can instead use it to design and build a prototype system to test or implement the theory in solving the IS problem (see second to fifth steps).
2. Create the concept for the proposed system.
3. Design and develop the proposed system.
4. Apply and use the proposed system.
5. Evaluate the success of the proposed system in meeting one's research question or goals.

In this study, we accomplished the first two steps using the literature review. Thus, in the first step, we identified and used the literature related to indicators of human sex trafficking in ads to create an initial ontology. In the second step, we identified and applied the KM concept of using a set of strong filters based on the ontology in a KMS designed to assess a dataset of ads. In the third step, we created the prototype by actually generating the ontology/keywords and identifying processes for obtaining a dataset, verifying the ontology/keywords against the dataset, and applying the ontology/keywords in order to analyze that dataset. In the fourth step, we applied the prototype that utilized the ontology/keywords and the processes that we created in the third step to assess a dataset for identifying victims of human sex trafficking. In step five, we evaluated the results from the fourth step and the proposed system to determine if the proposed system could accurately identify victims of human sex trafficking.

Literature Review Method

We identified the appropriate literature using the following search terms in various combinations: “sex trafficking”, “human trafficking”, “United States”, “America”, “California”, “online”, “Internet”, “social media”, “backpage”, “craigslist”, “classifieds”, “ontology”, “emojis”, and “technology”. We began the literature review using Google Scholar to find papers that have received a high number of citations and

to establish a baseline of pertinent literature. We conducted further searches using databases such as Ebscohost-Academic Search Premier, Scribd, and JSTOR. We used papers' references that particularly related to this study to find other similarly related papers. Finally, we searched the *Journal of Human Trafficking*'s archives.

Interview Method

As follow up to the literature review, we conducted unstructured interviews with law enforcement and individuals involved in efforts to combat online human sex trafficking and with academic researchers with expertise in the area of technology and human trafficking. Specifically, we interviewed a San Diego County's Sheriff's Department sergeant who was a member of their joint-agency human trafficking task force and two University of Southern California faculty members involved in Department of Justice and Humanity United-funded research projects focused on creating a better understanding of the role of technology in human trafficking activities and the use of data analytics to combat sex trafficking. We selected these interview subjects based on their availability, and a single interviewer conducted them in order to avoid bias. The interviews consisted of two-open ended questions:

- Explain your main areas of research/methods for targeting and identifying online trafficking activities?
- How have you applied your knowledge of the language that traffickers use (ontologies) to efforts to combat or identify online sex trafficking activities?

Based on their responses, we asked the respondents to expand on certain areas that we deemed required a more detailed explanation. We intended these interviews to confirm the practical application of theory identified through the literature review and identify any additional knowledge areas the theory did not address. We identified several highlights. First, the human trafficking task force believes that an ad that features a sex worker as 25 years old or younger is most likely a minor. Second, the interviewees noted that one needs to consider the social implications in using technology to identify online human trafficking. Finally, they discussed the difficulty in distinguishing between trafficking and non-trafficking ads and the best approach to address this issue.

SYSTEM PROTOTYPE DEVELOPMENT

KM focuses on producing actionable intelligence. In this research, the actionable intelligence is the identification of ads that identify victims of human sex trafficking. To obtain this actionable intelligence, we created a KM strategy that used the system development methodology. This strategy required a system that applied strong filters to a large unstructured dataset of "women seeking men" ads to eliminate those from genuine individuals. We identified the "women looking for men" section of backpage.com from various southern California cities as our data source. The initial system prototype used an initial ontology of keywords generated from the human trafficking literature as strong filters to demonstrate that it could identify potential trafficking victims. We refined the prototype by using expertise to refine the ontology and by applying text mining/machine learning to verify the ontology of keywords and remove words that all or most ads included. Additionally, we identified that emojis were being used in lieu of

or in addition to keywords. The emoji codes were added to the data analysis. We reapplied the refined ontology (keywords and emojis) as strong filters against a second unstructured dataset to demonstrate again that the system could identify trafficking victims from ads. Also as part of the strategy, we developed processes to extract an unstructured dataset and for applying the strong filters to the unstructured dataset to produce the desired actionable intelligence. In Sections 4.1 to 4.3, we describe how we created these strategy/prototype components.

Creating the Ontology/Keyword Set

To create an ontology/keyword set that could act as strong filters, we used a two-stage process with two different datasets. First, we used the keywords we identified (see Section 2.2) to identify which words from that list were in the first dataset. We extracted the keywords from each ad. To extract ethnic/nationality data, we used keywords in the filter feature of Microsoft Excel from both the text and title columns. We joined the Excel file to an area code location table to determine the origin of the phone number. We individually searched for area codes that the table did not represent online using Google. We used area code information to determine possible movement of providers. In all, 84 percent of the ads produced phone numbers, and we manually extracted another 12.6 percent because the ads disguised the phone numbers in some way. Ads often put random characters between numbers, write out the word, or use letters rather than numbers. Finally, 3.5 percent listed no phone number. We used the resulting list as the ontology/keyword set:

- Movement between cities included:
- **Transient Language:** new in town, just arrived, visiting, in town for the weekend two nights only, new arrival, new arrived, Brand new, limited time
- **Group Work:** Staff, ask for, my friend, sister, we, our, assistant
- Phone number, actual numbers from the dataset (used for three indicators: duplicate phone number, disguised phone number, out of state area code)
- **Restrained Movement:** Incalls only, incall only, only incall, no outcall, contains incall but does not contain outcall
- **Minor Indicators:** Little girl, youthful, sweet, young, college student girl, new in town, fresh, turned 18, only 18, fantasy
- **Unconventional Sex:** Open minded, fetish, kinky
- **Ethnicity:** White, Black, Asian, Islander, Caucasian, African American, Latina, Hispanic, mixed

After reflecting on the first ontology, we realized that the ontology would not be permanent and continue to evolve, especially when the traffickers realized what their words could identify trafficking victims (see Section 5.2.3). Thus, we decided to obtain a second dataset to verify the first stage ontology keyword set and to prototype applying the strong filters using R-based script. We verified the ontology keyword set from the first stage by applying experience from policing and research of human sex trafficking through unstructured interviews with human trafficking experts. Additionally, we used the text-mining module in R to parse the unstructured data to remove stop words and words that all or most ads included. The key issue was discriminating between keywords used in generic solicitations versus those used in marketing victims of human sex trafficking. The impact of these actions resulted in the 9 indicators in the initial ontology being reduced to 6 indicators for the revised ontology. The final ontology is:

- Sale of Services: Donation(s), price, rose(s), dollar(s), jacks, jacksons, hundreds
- **Minor Victims:** Fresh, young, new, tiny, little, new in town, girl, college
- **Ethnicity:** African American: AA, African American, Brown Sugar, Black (Beauty)
- **Asian/Pacific Islander:** Pocahontas, Asian, Pacific Islander
- **Caucasian:** Caucasian, White, European
- **Latina:** Latina, Hispanic
- **Country of Origin/Nationality:** South/East Asia, Eastern/Western Europe, Central America
- **Transient Activity/Movement of Victims:** New in town, just arrived, weekend only, limited time, new arrival, brand new, in town for the weekend, gone, back, leaving soon, only for the weekend, new
- **Non-Independent Worker/Restricted Movement:** Incall only, no outcall, only incalls, come to me, my house

Also, while analyzing the second dataset it was noted that there were emojis in the text and that in many cases the emojis seemed to occur with human sex trafficking keywords. The evaluation of emoji indicators also involved the use of the tm package in R to build a Term-Document matrix with the corpus of ads with each emoji indicator. In order to create a framework for filtering out terms in ads that are not likely to be related to human trafficking, we identified the terms that occurred most frequently across all documents in the corpus to remove from the corpus before analysis. To do this the Term-Document matrix was used to remove sparse terms and then identify the most frequently occurring terms as they are less likely to be specific to human trafficking. These words were selected by identifying not only at the most common terms within the corpus, but also the terms that were present in ads without any indicators of human trafficking. Words common in both these elements were identified as being part of the general ontology for any classified ads related to the provision of sexual services or casual dating and not specific to sex trafficking. For validation of these results, the study looked not only at the most common terms within the corpus, but also the terms that were present in the majority of the documents.

A knowledge management approach was then used to identify emojis in ads likely to be linked to human sex trafficking. Clusters of ads with and without keywords associated with human sex trafficking indicators were built by applying natural language processing methods to the unstructured dataset. These clusters then determined the frequency of the emoji occurring in each cluster. Ad significance was then determined through logistic regression analysis and t and z tests.

Process for Extracting the Unstructured Dataset

We created the first unstructured dataset by scraping Web advertisements from websites known to post sexually explicit solicitations/ads. To make it usable for analysis, we converted the scraped data into a .csv file then manually processed into a Microsoft Excel file for analysis.

After reflection, we obtained the first dataset mostly through a manual process, which we considered unsustainable for an automated system approach, so we decided to create a second dataset to test the revised ontology. As such, we created an automatic Web-scraping tool with various approaches. However, this method did not work well because the target websites blocked automatic Web scraping. As a result, we scrapped the automated Web scraping and repeated the manual process to obtain a .csv file with the raw data. We then processed the raw data file using Excel to remove duplicate postings (in this

study, we analyzed content and not frequency, so multiple postings would bias the results) and to identify records with missing data. We loaded the resulting processed raw data file into R's machine-learning and text-mining functions to remove stop words contained in the English stop word dictionary and to identify words common to all ads.

Process for Applying the Prototype

We developed a simple process that involved actual keyword counts to apply the ontology/keyword set to the unstructured dataset. We used count functions in Microsoft Excel to generate the number of times keywords appeared and to determine if an ad contained a trafficking indicator. We also used other mathematical functions in Microsoft Excel to generate results such as the percentage of ads that contained the keyword.

After reflection, we modified this process for the second prototype. Instead of using Excel to do word counts, we used R to code each add with a series of 0 or 1 codes. R coded each human trafficking victim indicator 0 if an ad contained no ontology/key word indicators or 1 if an ad did contain ontology/keyword indicators. R then summed the number of victim ontology/keyword indicators for each add. By using R to code the dataset, we could automate the analysis portion of the prototype.

APPLYING THE PROTOTYPE

Creating the Dataset

The first application of the prototype used a dataset that we extracted from backpage.com for several cities in California. We chose California because we live in the state and because it is a major hub for prostitution and sex trafficking. California encompasses many ports of entry and lies adjacent to the Mexican border region, which is rife with human trafficking (Goldenberg, et al., 2014).

We gathered data for the study by scraping from the “female escort” section of backpage.com from 11 to 16 February, 2015, across 15 different California cities/counties: Bakersfield, Chico, Fresno, Los Angeles,

Merced, Oakland, Orange County, Sacramento, San Diego, San Francisco, San Jose, San Luis Obispo, Santa Barbara, Santa Cruz, and Stockton. Some errors occurred in the data-scraping process. San Diego only produced about two-and-a-half days of data due to an error, so the data sample for that city was smaller than that for the other large cities. In total, we scraped a total of 5,633 ads. We then processed the data as we discuss in Section 4.2.

After reflecting on the first dataset, we collected the second dataset from the “women seeking men” section of the dating classifieds on backpage.com. The sample included advertisements posted between February and March, 2017, for three major cities/counties in Southern California: San Diego, Los Angeles, and Orange County. We selected this sample because of the close proximity of the three cities, which makes the language used in the advertisements subject to less variability due to regional language differences. The initial dataset included 8,940 records that we processed in accordance with Section 4.2; as a result, 8,744 records remained in the final dataset.

ANALYZING THE DATASET

Analyzing the First Dataset Using the Initial Prototype

We analyzed the first dataset as we discuss in Section 4.3. Specifically, we compiled keywords that indicate possible minor sex trafficking and analyzed them against the advertised age. We combined all ages past 30 into one group as the large majority of ages were between 20 and 25. Note that the advertised ages are not necessarily accurate, especially in trafficking situations. Traffickers may be more likely to advertise a victim of minor sex trafficking as being aged from 20 to 25—young enough to still attract the correct buyer but old enough not to raise law enforcement suspicion. Overall, we found a number of prominent age terms such as “sweet”, “young”, and “fantasy”; rarer terms included “only 18”, “turned 18”, “very young”, and “little girl”. Traffickers would not likely use the rarely used keywords for fear of attracting law enforcement. Additionally, terms such as “college student/girl”, “new in town”, and “fresh”, seem to skew slightly toward younger ages, which could indicate younger individuals.

Many ads had multiple keywords. Out of the sample of 5,633 ads, 4,836 had a least one indicator of human sex trafficking. By far the most prominent indicator was “duplicate phone/ad”. These results are similar to those that Latonero et al. (2012) found. Specifically, these authors found that a small number of phone numbers accounted for a disproportionate amount of ads; however, on reflection, we believe that this disproportion reflects people’s practice of keeping their mobile number even after moving and provides little information with respect to victims of human sex trafficking. As such, we can conclude that a single indicator of human sex trafficking cannot sufficiently identify a potential victim and that duplicate phone/ad by itself does not provide enough discerning information to identify a victim of human sex trafficking but that it is likely to be a good indicator in combination with other indicators. The following list includes the percentage of total ads with the specified indicator present:

- Duplicate ad/phone number (54.8%)
- Ethnicity/national origin (44.9%)
- Unconventional sex (13.4%)
- Disguised phone number (12.5%)
- Out of state area code (12.1%)
- Restriction on movement (11.8%)
- Transient language (9.0%)
- Indications of working in a group (8.8%)
- Minor keyword indicators (5.2%)

The following list shows how many ads had multiple indicators (out of nine indicators):

- 4,836 had at least one indicator
- 3,126 had at least two indicators
- 1,354 had at least three indicators
- 330 had at least four indicators
- 74 had at least five indicators
- Eight had at least six indicators
- One had seven indicators.

Analyzing the Second Dataset Using the Revised Prototype

We analyzed the second dataset as we discuss in Section 4.3.

The following list shows percentage of ads with the indicated keyword indicator:

- Sales of service (1.56%)
- Minor (48.2%)
- Ethnicity (30.3%)
- Country of origin (11.4%)
- Transient language (12.67%)
- Restriction of movement (0.71%)

The following list shows how many ads had multiple indicators (out of 6 indicators):

- 3,534 ads had at least one indicator
- 1,768 ads had at least two indicators
- 467 ads had at least three indicators
- 33 ads had at least four indicators
- Two ads had five indicators

To compare the ontology to the emojis the subset function in R was used to create two populations of ads, one with known indicators of trafficking and the second without indicators of trafficking. These known indicators consisted of keywords/phrases in the ontology used. The indicators of human sex trafficking are: sale of services, minor/underage victims, ethnicity/race, country of origin, transient activity/movement of victims, and non-independent workers/ restricted movement.

- **Ontology Development Identified:** (Note that ethnicity and country of origin emojis are common across all ads and no special emojis were found specific to human sex trafficking)
- **Two Emojis:** The rose and the rosette for the keyword indicator of sale of services.
- **Three Emojis:** The growing heart emoji, cherry emoji, and cherry blossom emoji for the minor keyword indicator
- One emoji, the airplane emoji was the only significant indicator for the keyword indicator of transient activity
- One emoji, the crown emoji was found significant for keywords associated with restricted movement/non-independent.

The following list shows how many ads had multiple emoji indicators:

- 2,237 ads had at least one indicator
- 790 ads had at least two indicators
- 216 ads had at least three indicators
- 36 ads had at least four indicators.

Finally, looking at both keywords and emojis we get the following list having multiple indicators

- 1,825 ads had at least three indicators
- 509 ads had at least four indicators
- 127 ads had at least five indicators
- 37 ads had at least six indicators.

DISCUSSION

It is shown that keywords and emojis can be used as indicators of sex trafficking. It is observed that the number of ads with multiple indicators dropped quickly the more indicators that were identified. This was an expected result that illustrates that the process works. Comparing the number of ads with multiple indicators to the 792 reported cases of human sex trafficking in California in 2015 (NHTRC, 2016) and 544 human sex trafficking cases in the first half of 2017 (Polaris Project, 2017) suggests that one can establish a threshold number of indicators that indicates a possible sex trafficking victim. The first dataset suggests either four or five indicators as the threshold (out of nine indicators). Four is a conservative threshold that will not likely miss any victims but will probably include many false positives on potential victims because, in the sample, 330 ads had four indicators (about 40% of the yearly number of reported sex trafficking cases). Using five or more indicators strongly suggests a victim of sex trafficking: in our sample, five or more indicators yielded 74 potential victims (or 9.3% of the yearly number of reported sex trafficking cases). Given the limited resources available to law enforcement, a more focused number, although it may miss some potential victims, may be better. This logic suggests that four indicators (out of six) in the second dataset as the threshold because 33 ads is about six percent of the 544 cases reported in the first half of 2017. Finally, if using a full ontology including emojis and keywords it is recommended that a threshold of 6 indicators (either emoji or keyword) be used. To sum up, it is recommended that five indicators (when one uses nine indicators total), or four (if one uses six indicators in total), or 6 indicators (if using emojis and keywords) be used as a threshold for recommending law enforcement intervention.

We also observed that, while phone-based indicators seemed to be useful in the first dataset, we removed them from the revised ontology for the second dataset. We removed duplicated phone numbers as an indicator because this indicator did not discriminate between trafficking phone use and regular prostitution phone use well enough. We dropped the other phone indicators (i.e., blocked or disguised phone numbers or out of area phone numbers) because it is becoming too common of a practice to use-fully serve as an indicator (i.e., many people now commonly block or disguise their phone number for privacy and security reasons, and carriers now commonly allow customers to keep their phone numbers when they relocate). Conversely, we have a concern that the indicators do not do a good enough job discriminating between voluntary prostitution and sex trafficking victims. Ethnicity and to a lesser degree country of origin and minor indicators (especially in the second dataset) do not discriminate between sex trafficking victims and voluntary prostitution and only work in conjunction with other indicators, which strengthens the argument for using at least four (when using six in total) or five (when using nine in total) indicators for initiating follow-up actions.

We used backpage.com for this research as a case study, but it only accounts for a portion of all online escort ads. We created a prototype that can be implemented into various websites. The difficulty in using it rests in the data-extraction process as we observed when we attempted to use craigslist.com. It may be possible to use the data-extraction process only when generating/validating the ontology and using the analysis process as a constant online monitoring and alarm tool.

EVALUATING THE PROTOTYPE

The prototype was evaluated by reflecting on the outcomes generated when applying the prototype to a real dataset. As a result, a revised dataset was created and tested. Reflection on these results when compared to outside reports on the numbers of human sex trafficking victims resulted in the recommended thresholds (see Section 5.2.3) to use to identify potential victims of human sex trafficking. Additionally, the system development methodology includes a five-step evaluation process (Burstein & Gregor, 1999) for assessing the quality of the system development methodology process. This assessment is described below. Overall, it is noted that the proposed prototype is acceptable as an output of the system development methodology as it met all steps of the five-step evaluation process.

Significance

Outcomes/artifacts from the system development research methodology should yield significant theoretical contributions, a system that yields better results than those systems currently in use, or both. In our case, we created the latter—a significant practical contribution that yields better results than the ones that currently exist.

Currently, law enforcement agencies search adult service classified ads to find to find pictures of people that look as though they are being trafficked (Latonero et al., 2012). Commonly, law enforcement agencies begin investigating possible sex trafficking by browsing through ads and looking for girls with pictures that look very young. If the girl looks underage, they may open an investigation (Latonero, 2011). They also compare an advertisement's picture with the advertised age. If they perceive a discrepancy between a girl's picture and her advertised age, law enforcement agencies may also open an investigation. Although these techniques have been one way to locate potential victims, they suffer from complications. First, it is extremely tedious and, second, photos are not always accurate (Latonero, 2011). While many law enforcement agencies use these tactics with some success, the system proposed in this chapter may identify more potential victims without generating large numbers of false positives. It is evaluated that the proposed ontology/system has practical significance.

Internal Validity

Internal validity refers to the credibility of one's results and whether they make sense. Established theory was used to generate an ontology that was applied to an unstructured dataset with the results presented in this chapter. The presented results are consistent and expected given the theory used and its application to the problem.

Further, to verify internal validity, rival methods were considered. Other work that has investigated this research area was reviewed, but it has all used some form of ontology-based method for identifying potential victims. For instance, Ibanez and Suthers (2014) used escort advertisement data to evaluate the significance of known indicators of online trafficking activity. They found that ads that contain two or more indicators are more likely to be instances of trafficking and that the most prevalent indicators for trafficking in order are ethnicity/nationality, potential restricted movement, movement along trafficking circuit, and shared management (multiple providers). Dubrawski, Miller, Barnes, Boecking, and Kennedy (2015) trained multiple random forest models using three different information-extraction approaches, termfrequency analysis using law enforcement provided keywords, regular expressions, and machine learning to weight 115 keywords. Alvari, Shakaria, and Snyder (2016) used a sample advertisements

posted on backpage.com in March, 2016, to train a learning classifier. They used a semi-supervised learning algorithm to label the remaining advertisements and had experts in online sex trafficking review the classifications to evaluate accuracy. Considering Alvari et al. (2016), natural language processes and text mining in the prototype were added for the second dataset.

External Validity

External validity concerns “the generalizability of a causal relationship to and across populations or persons, settings, and times” (Burststein & Gregor, 1999, p. 134). To test external validity, the developed prototype was applied across a variety of nationalities and ethnicities but all in the state of California. It is conceded that the prototype can be applied to any population/ad sample in the United States, but it may not be generalizable directly to other cultures. We do believe the indicators are applicable for other cultures and countries, but would need to adjust the ontology to fit their language(s)/culture(s). Using the AI and machine learning approaches incorporated into the second prototype provides a means for identifying and adjusting indicator terms based on language and culture differences. Thus, it is noted that the revised prototype has external validity for the United States and has external validity for other cultures/countries when one adjusts the prototype processes for culture/country.

Objectivity/Confirmability

Objectivity/confirmability concerns ensuring research does not suffer from researcher bias or that the researcher at least reports and discusses them. By basing the indicators on the literature and then generating the ontology by using the words in the extracted data, we removed much of our own bias for our prototype. Further, we used machine learning and text mining in the revised prototype to further reduce it.

Reliability/Dependability/Auditability

Reliability/dependability/auditability concerns quality control. The system was developed using a process that is consistent and stable across researchers and methods. We relied on the literature and the accepted system development research methodology to generate the prototype. Thus, it is concluded the prototype has sufficient reliability, dependability, and auditability.

CONCLUSION

It is concluded that the prototype works and that it deserves further development. We found that the prototype meets the requirements of the system development methodology from action research and that it yields promising results when tested against actual datasets. We also recommend that an alert/warning system be developed based on this research that can provide a warning when ads contain five or more indicators (when using the nine ontology), four or more indicators (when using the six ontology), or six or more indicators (when using emojis and keywords)—thresholds determined based on comparing the number of ads the indicators identified with the number of reported victims (i.e., 792 for the first dataset (NHTRC, 2016) and 544 for the second dataset (Polaris Project, 2017)). We expect the suggest alarm system to result in a low number of positive alarms.

Further, we conclude that the system development method, especially when used with KM, is a viable approach to conducting research into developing systems to solve social problems. We found the method very useful for taking the emphasis off the application of new technologies and keeping the research focused on solving a social problem and building a system to do so.

IMPLICATIONS FOR RESEARCH

The initial prototype is a proof of concept, while the revised prototype moves towards an automated system; however, neither creates any new theory. Research focused on integrating more advanced technologies into a KM system for generating actionable intelligence that authorities can act on could generate significant social benefit. Specifically, we need future research that further focuses on automating the prototype's data-extraction process. A framework for developing the full automated system should be developed based on this research and the framework presented in Jennex (2017), a proposed KM model based on a modified knowledge pyramid.

IMPLICATIONS FOR PRACTICE

Finding victims of human sex trafficking is difficult and requires all the technology innovation possible. The practice of using posted photos and facial recognition is not working well and needs improvement. This study suggests how technology in practice can be used to identify victims of sex trafficking. Practitioners will need to adapt to the processes that we illustrate in the paper and to adapt their intelligence gathering and investigative techniques to take advantage of the technology we prototyped.

LIMITATIONS

This study has two major limitations. First, only female victims were considered. While we recognize that males can also be victims of human sex trafficking, males were not included in the study because we sought only to demonstrate that a KMS could be used to identify victims and considering males made the project more complex than needed.

Second, we cannot prove conclusively that the potentially identified victims were in fact real victims. Given ethical concerns with the research, we could not actively interview rescued victims or actively search for victims.

Both limitations may impact the generalizability of the proposed system but are considered acceptable for this research.

AREAS OF FUTURE RESEARCH

Researchers could extend our findings by investigating at least two areas. First, researchers could examine male victims to determine if the indicators and keywords differ from female victims. Second, they could investigate technologies that can be used to create an automated KMS. We used Excel to conveniently demonstrate a proof of concept in the initial prototype. The second prototype incorporated text mining

and machine learning to assist in automatically generate an ontology and analyze data. Thus, our approach experienced weaknesses in extracting data, and future research needs to develop and automate the data-extraction process.

Additionally, data from online adult service ads can be used to inform the study of the commercial sex industry and, consequently, sex trafficking. The data we gathered shows indications of the geographic trafficking patterns across state borders and the demographic makeup of many individuals. This information can help identify previously unknown trends in sex trafficking.

ACKNOWLEDGMENT

Earlier versions of this research were presented at the 49th and 51st Hawaii International Conferences on Systems Sciences, HICSS, in January, 2016 and 2018. Additionally a journal article version of this paper without addressing emojis was published in Communications of the Association of Information Systems in 2018.

KEY TERMS AND DEFINITIONS

Emoji: A small digital image or icon used to express an idea, emotion, etc.

Filter: The implementation of KM strategy. A method used to separate the big data, data, information, or knowledge needed to make a specific decision from unneeded big data, data, information, or knowledge.

Human Sex Trafficking: Inducing others to perform a commercial sex act by force, fraud, or coercion; as inducing a person under 18 years of age for such an act; and/or as recruiting, harboring, transporting, providing, obtaining a person for labor or services through the use of force, fraud, or coercion in order to subject them to involuntary servitude, peonage, debt bondage, or slavery (National Institute of Justice, 2012).

Ontology: Knowledge codified by providing a simplified and explicit specification of a phenomenon that one desires to represent (Gruber, 1995; Noy & McGuinness, 2001; Staab et al., 2001).

INTRODUCTION

The era of digitalization is collectively becoming more of a vehicle for exploitation and criminal activities. That said, transnational criminals are increasingly utilizing the darknet or deep web as a medium for human trafficking. Human trafficking is a global problem and the solution requires a comprehensive response to tackle this borderless crime. In 2018, the U.S. State Department Trafficking in Persons (TIP) Report, ranked Malaysia a Tier 2 Watch List country because the “government of Malaysia does not fully meet the minimum standards for the elimination of trafficking; however, it is making significant efforts to do so”. In Malaysia, women, children, and migrant workers are exploited at every stage of the human trafficking process because of their vulnerability. Especially relevant now is the sophistication of human trafficking in the darknet or deep web. With global society becoming more technologically advanced, traffickers have been able to facilitate much of their criminal activity through technology, which provides both anonymity and access to communication with the entire world (Barney, 2018). That said, cyber laws in conjunction with federal and international laws require constant reviews in order to protect the victims of trafficking. This article reviews the literature on human trafficking, the existing legislations and their effectiveness in Malaysia to combat human trafficking in the internet and deep web. The article analyses the existing policies, Malaysia laws and international laws and instruments that are available to prevent and protect women, children and migrant workers from being trafficked. This article will also suggest the necessary measures to prevent human trafficking in Malaysia.

DOI: 10.4018/978-1-5225-9715-5.ch035

BACKGROUND

3

Human trafficking is often referred to as a modern form of slavery. Furthermore, it is considered a highly lucrative criminal activity and countries with large sex industries create the demand, supply and destination for trafficking in persons. Traffickers often target vulnerable women, children and migrants who seek for better employment and opportunities (Zimmerman & Kiss, 2017). Therefore, it is difficult to draw a line separating trafficking from free choice or voluntary illegal migration or prostitution. Malaysia is a source, transfer and destination country for a significant number of men, women, and children who are trafficked from Indonesia, Thailand, Philippines, Cambodia, Vietnam, Burma, People's Republic of China, India, Nepal, Bangladesh, and Pakistan for sexual and labor exploitation (U.S. Department of State, 2018). Many victims voluntarily migrate to Malaysia to work in factories, construction and agricultural sectors, or as domestic servants, but are later coerced into debt bondage or involuntary servitude (U.S. Department of State, 2018). Currently, the technology growth and use of information and communication technologies (ICTs) have been accompanied by an increase in exploitation and abuse of technology for criminal activities. With regard to cyberspace, the internet is increasingly used by transnational organized criminals for human trafficking (Voronova & Radjenovic, 2016). Trafficking in persons is an obvious form of organized crime that has been affected by the globalized revolution in ICT (Tan, Khan & Abdul Rahim, 2014). Illegal trafficking is not exclusive to sexual exploitation with respect to women or child trafficking, but also covers indentured servitude and child labor (Tan et al., 2014). ICTs such as using the internet and mobile phones are frequently used as a tool for human trafficking since internet control is almost borderless and convenient for human traffickers to operate the trafficking *modus operandi* (Toney-Butler & Mittel, 2018).

The era of digitalization and internet have enabled the organized crime of human trafficking to become more challenging for law enforcement agencies and governments. Law enforcement agencies around the world are largely not prepared for combatting cybercrime due the anonymity of the internet or deep web. The deep web or darknet is considered the hidden part of the internet that cannot be found using traditional search engines such as Google. It can be accessed only via software such as The Onion Router (TOR) without exposing the users' Internet Protocol (IP) address and is used to intentionally hide user identities to participate in illegal trade of guns, drugs, sex, counterfeit money, etc. (Formoso, 2017). Thus, making the internet or deep web alluring for cybercrimes and a vehicle for human trafficking. Furthermore, provide a convenient method for cybersex predators to indulge in their deviant behavior (Plaza, 2015).

Inadequate law enforcement facilitates criminals to exploit victims in the deep web. Due to this flaw, elements of human trafficking can be conducted in the deep web, such as: "exploitation of children for the production of pornographic material, online brides and marriage agencies" (Witting, 2017). Human trafficking in the cyber realm presents devastating legal dilemmas. For instance, because a child posing online conducting sexual acts is considered a victim of child pornography offence. Nevertheless, child pornography offences are often not systematically criminalized under the respective national legislation, which leaves a legal gap and often perpetrators are not charged. Furthermore, prosecutors have considered whether cyber trafficking cases, such as online child sex tourism, can be defined as human trafficking (Witting, 2017).

HUMAN TRAFFICKING

Human trafficking is a spreading and worsening global phenomenon. Women, children and migrant workers are trafficked and exploited worldwide, largely into the sex industry and forced labor. Although approximately 4% of the world's 30.2 million trafficking victims at the end of 2010 were trafficked for sex, those individuals generated approximately 40% of the 96.8 billion in profits generated by human trafficking during 2010 (Bailey, 2018). Data released by the International Labor Organization (ILO) estimated that forced labor in the private economy, including for sexual exploitation, generates 150 billion dollars per year in illegal proceeds (Bailey, 2018). Current global trends in online payment and fast, online information transmission increase the likelihood that human trafficking will only become increasingly profitable in the coming years (Bailey, 2018). While the international community condemns human trafficking and considers its practice unacceptable, trafficking today is stronger and more pernicious than in the past. The causes of trafficking are complex because traffickers are organized crime syndicates. Nevertheless, the main contributing factors of human trafficking include: unequal economic development of countries; adverse impact of globalization processes on less developed countries, which aggravate widespread poverty and inequality; and discrimination and gender based violence perpetrated by patriarchal institutions in societies. Human trafficking is facilitated by: the mobility of people in search of better employment and a better life; the spread of new information technologies; and in the case for sex trafficking, by sexual exploitation becoming more pervasive in every region of the world. Human trafficking is controlled by organized crime and syndicates with multi-layered intermediaries at the local and international levels. The general reasons causing human trafficking are:

1. The devaluation of vulnerable women, children, migrants and discrimination practices
2. The perceived responsibility to support families
3. Lack of educational, employment and vocational opportunities.
4. Globalisation where the rich take advantages of the poor.
5. Lack of laws and enforcement e.g. free trade zone allows free movements and attracts negative forces to the countries.

Criminal syndicates have devised ways to defeat systems set in countries to prevent illegal immigration or human smuggling by incorporating corrupted officials within the country's border control or immigration department. Travel documents provided to victims are authentic through means of the corrupted officials, and other times are counterfeited through technologies. Women, children and migrants sometimes illegally migrate by crossing through several transit countries, making it more difficult to trace them. It is very difficult to trace missing trafficked victims, especially when they possess legal travel documents and the security system at the border control is weak.

The following are definitions of Trafficking in Persons and Smuggling of Migrants according to Malaysia's Anti-Trafficking in Persons and Anti-Smuggling of Migrants Act 2007:

Trafficking in persons means:

all actions involved in acquiring or maintaining the labor or services of a person through coercion, includes the act of recruiting, conveying, transferring, harbouring, providing or receiving a person. (Malaysia Anti-Trafficking in Persons and Anti-Smuggling of Migrants Act 2007).

Smuggling of migrants means:

arranging, facilitating or organising, directly or indirectly, a person's unlawful entry into or through, or unlawful exit from, any country of which the person is not a citizen or permanent resident either knowing or having reason to believe that the person's entry or exit is unlawful and recruiting, conveying, transferring, concealing, harbouring or providing any other assistance or service for the purpose of carrying out the acts mentioned above. (Malaysia Anti-Trafficking in Persons and Anti-Smuggling of Migrants Act 2007).

The magnitude of human trafficking in Malaysia, and the forms of trafficking such as child labor, debt bondage, brides order and sex slave today are more alarming than ever. This “modern-day slavery” surpasses the slave trade of the past in that it has become associated with other criminal activities, such as drug/arms trafficking. Estimates of the number of trafficking activities vary greatly because of the difficulty of data collection for this clandestine activity. Trafficking occurs within countries as well as across national boundaries. The lucrative extent of trafficking and the loose policies to track this organized crime have made it more challenging for the government and non-profit organizations to combat human trafficking in Malaysia.

U.S. STATE DEPARTMENT TRAFFICKING IN PERSONS (TIP) REPORT

The annual Trafficking in Persons (TIP) Report published by the U.S. State Department is a report that ranks all countries from Tier 3 (lowest) to Tier 1 (highest) based on their compliance to the minimum standards set forth in the U.S. Trafficking Victims Protection Act 2000, Div. A of Pub. L. No. 106-386, § 108. The U.S. Trafficking Victims Protection Act (TVPA) attempts to combat trafficking on an international scale together with its annual Trafficking in Persons report. In short, the minimum requirements are:

1. Trafficking in persons are prohibited by the government and is punishable.
2. The punishment prescribed by the government is commensurate with that for “grave crimes, such as forcible sexual assault”.
3. The government should prescribe stringent punishment for anyone with knowledge of “commission of trafficking in persons, to deter and that adequately reflect the heinous nature of the offense.”
4. The government should make “sustained efforts to eliminate severe forms of trafficking in persons”.

The above are known as “the 4Ps”, which under the TIP Report framework, effective anti-trafficking laws are those that:

(1) protect victims, (2) prosecute traffickers, (3) prevent future harms, and (4) utilize community partnerships to combat trafficking.

In determining a country's compliance with these minimum standards, the U.S. State Department considers where countries typically rank in the global supply chain for trafficking (origin, transit, or destination for trafficking); the extent to which government actors were involved or complicit in the trafficking; and what measures are reasonable given a country's economic situation (Bailey, 2018).

MALAYSIA ACCORDING TO U.S. TIP REPORT

In 2011-2013, the U.S. State Department Trafficking in Persons (TIP) Report ranked Malaysia a Tier 2 Watch List country. In 2014, Malaysia was downgraded to Tier 3, which is the lowest grade for countries “not making sustained efforts to comply with the minimum standards to address trafficking” as described in the U.S. Trafficking Victims Protection Act (TVPA). The consequences for countries listed as Tier 3 include denial of non-humanitarian aid, development related assistance and exclusion to enter trade agreements with the United States. In 2015, Malaysia was upgraded to Tier 2 Watch List, which was criticized in the international arena (Renshaw, 2016). The following year, Malaysia maintained its rank of Tier 2 Watch List in 2016. In the 2017 TIP Report, Malaysia was placed at Tier 2; however, because the Malaysia government did not demonstrate overall increasing efforts compared to 2017, the country was again downgraded to Tier 2 Watch List in 2018 because “the government of Malaysia does not fully meet the minimum standards for the elimination of trafficking; however, it is making significant efforts to do so”.

Furthermore, the 2018 TIP Report mentioned that although the Malaysia government “convicted more traffickers, increased criminal enforcement of unauthorized passport retention, granted more victims freedom of movement, tripled funding for NGOs including for three NGO-run shelters, and opened its first trafficking-specific court, and amended its foreign worker levy and Private Employment Agency Act to shift debt burdens away from migrant workers”, the efforts were not enough because it did not “demonstrate overall increasing efforts compared to the previous year”.

According to the 2018 U.S. TIP Report, the Malaysia Trafficking in Persons statistics from 2015-2017 are seen in Table 1 below:

Malaysia’s anti-trafficking efforts may appear less in the 2018 reporting period than its efforts in the previous year; however, in March 2018, the government established an anti-trafficking court for the state of Selangor. The state of Selangor was selected due to its history of having the highest trafficking in persons cases. Moreover, the Malaysia government expanded its directive of interagency law enforcement task force and made it permanent. The task force successfully conducted six operations focused on forced labor in 2017 with the lead enforcement agency as the Royal Malaysia Police. Furthermore, the “Malaysia government conducts or support anti-trafficking trainings, including 34 in-service trainings for police officials and 14 transnational or bilateral trainings in the region focusing on victim protection, law enforcement, and prosecution” (U.S. State Department, 2018).

Even with the above efforts by the Malaysia government, collusion still exists among law enforcement officials with human traffickers i.e. officials accepting bribery in exchange for undocumented border crossing. In 2016, the Malaysia government prosecuted five officials for accepting bribes and four were found guilty for smuggling offenses, while the fifth was acquitted.

The reason for the high potential trafficking victims is because enforcement agencies employed the Malaysia anti-trafficking law broadly by presuming all foreign women during bar or massage parlor raids

Table 1. Malaysia trafficking in persons statistics (2015-2017)

	2015	2016	2017
Trafficking and Tracking Related Investigations	158	581	556
Prosecutions Initiated	38	175	80
Convicted traffickers	7	35	45

Note: From U.S. Trafficking in Persons Report 2018. Retrieved March 30, 2019 from <https://www.state.gov/j/tip/rls/tiprpt/>

Table 2. Malaysia potential vs. confirmed trafficking victims (2016-2017)

	2016	2017
Potential Trafficking Victims	3,411	2,224
Confirmed Victims	1,558	721

Note: From U.S. Trafficking in Persons Report 2018. Retrieved March 30, 2019 from <https://www.state.gov/j/tip/rls/tiprpt/>

as potential victims. The decrease in overall victims identified may be due to the Malaysia government shifting resources toward forced labor vice to their previous focus, which was primarily on sex trafficking (U.S. State Department, 2018).

HUMAN RIGHTS COMMISSION OF MALAYSIA (SUHAKAM)

SUHAKAM is a Human Rights Commission of Malaysia and continues to support the Malaysia government's efforts to strengthen action against trafficking in persons. While Malaysia has laws to criminalize human trafficking, SUHAKAM 2017 Report questions the effectiveness of the implementation of these laws because trafficking in persons continues. In SUHAKAM 2017 Report, human trafficking and smuggling included 12 incidents in Peninsular Malaysia, and 2 in Sabah (SUHAKAM, 2017). Of the 14 cases reported, SUHAKAM addressed that 7 cases were referred to the Anti-Trafficking in Persons and Smuggling of Migrants (ATIPSOM) Task Force, which was established in December 2016, while the rest were not, "due to the lack of substantial information in the complaints as well as the complainants' lack of cooperation to provide further information when requested".

One of the cases referred to the ATIPSOM Task Force was a human trafficking syndicate operating from an apartment in Cyberjaya, Malaysia. Based on a tip off, the task force raided the apartment, arrested the traffickers and rescued five Nigerian women. In another case, the Thailand-based civil society, Alliance Anti Traffic (ATT) informed that they had intercepted the smuggling of two Shan girls in Thailand when they were being enroute from Malaysia to Vietnam. Later was informed that more girls were kept at a location in Ipoh, Perak, Malaysia. On 3 March 2017 based on a tip off, the police rescued 19 Shan girls and a Vietnamese, arrested three suspects and charged them under Section 12 of ATIPSOM on 10 March 2017.

THEORETICAL ASPECT OF HUMAN TRAFFICKING

The first international agreement on the definition of "trafficking in persons" according to the 2000 United Nations Convention Against Transnational Organized Crime Trafficking Protocol Article 3(a) is:

The recruitment, transportation, harbouring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. (United Nations, 2000, p. 42).

The term “exploitation” in this definition encompasses: sexual exploitation, forced labor, slavery, servitude and removal of organs. However, this article focuses on human trafficking and cyber laws.

Human trafficking is a form of modern day slavery because trafficked victims are exploited by force or under debt bondage. The point is that, “whilst the practices of trafficking are not central to the global transnational markets or the global world in which we live, as slavery once was, they are nevertheless embedded in the inequalities and injustices of the distribution of wealth promoted and encouraged by the world system” (Santos, Gomes & Duarte, 2010).

Means of Human Trafficking Through Technology/Internet

The means of human trafficking and sex exploitation via technology/internet are frequently used by traffickers due to its borderless recruitment process and larger target of victims around the world. Traffickers are using the internet to advertise their services and force them upon their victims. Craigslist, Facebook and chat rooms specific to these services are not uncommon. Online advertisement has been used by the perpetrator to lure their victims. While, some service providers use their victims to advertising themselves with both real and fake photos to mask under age exploitation. THORN, an NGO co-founded by Ashton Kutcher and Demi Moore to drive tech innovation to fight child trafficking and sexual exploitation reported that 63% of victimized kids are advertised online. The cost of recruitment is lower than the conventional recruitment/trafficked process.

The means of human trafficking through ICT are generally by fraud and coercion or ransom/blackmail. Not only the deep web or darknet are women and children coerced into human trafficking, the internet, where social media is accessed can start the process of human trafficking with a simple flattering comment (Baker, 2019). Such is the case with “Internet Romeos”, whereby traffickers groom their targets by building trust and a relationship with a potential victim. Once the victim is convinced the Romeo is in love, the victim is persuaded to move with him to a new town and manipulates the victim into forced prostitution (Baker, 2019).

The deep web hides your identity and location and may be accessed via a search engine such as TOR. TOR does not retain search engine records and leads the searcher to the desired website without any trace of who they actually are (Jardine, 2015). The dark net also includes assassination services, arms dealing, human experimentation and paedophilia and the means to pay for these service can be anonymous with prepaid debit cards and crypto currency.

Process of Human Trafficking Through ICT

Internet use for sex trafficking victim advertisements such as www.Backpage.com (Backpage) has become increasingly prevalent in recent years due to limited intervention by international government agencies (Kowalski, 2018). Such as the case with the United States government attempting to criminalize advertisements of minors for sex; however is blocked due to U.S. Constitutional challenges, Supremacy Clause, the First Amendment and Commerce Clause (Kowalski, 2018). According to the Thorn organization, victims recently recruited into the sex trade were facilitated by using internet transactions and while the adult section was removed from Backpage in the U.S. market in 2017, purveyors of sex trafficking have found a work around and instead post ads in the dating or massage sections on Backpage. Traffickers have also penetrated general websites such as Facebook to continue on with sex exploitation of women and children.

The process of human trafficking through technology/internet are:

1. Online Chat /Dark Web
2. Recruitment /Process by way of meeting the victims personally
3. The means are usually by force, fraud, coercion or drugs i.e. the push and pull factors in human trafficking.

Traffickers can exploit technology for their own illegal purposes as described above. Prior to the internet, traffickers were forced to reach consumers and conduct business through underground networks. Now, due to the anonymity of the internet or use of the deep web, both traffickers and consumers can conduct business online with minimal risk of being identified. The result is an increased market and consumption in the trafficking in persons industry. Individuals fearful of being identified, and potentially prosecuted for their involvement, can now access information and make connections anonymously from the safety of their own homes.

CYBER LAWS AND SECURITY POLICY IN MALAYSIA

While Malaysia cyber laws were established since 1997, law enforcement is not sufficiently equipped with the specialized knowledge to investigate the borderless nature of the cybercrimes, which continues to increase in Malaysia because there is a significantly lower risk of being detected or prosecuted” (Tan et al., 2014).

Malaysia is one of the earliest nations in Southeast Asia to develop a National Cyber Security Policy and one of the first nations in Southeast Asia to enact cyber laws. The Malaysia National Cyber Security Policy is said to be enacted in 2019. However, at the time of writing this article, Malaysia has not officially enacted its National Cyber Security Policy. The policy’s main objective is to “address the risks to the Critical National Information Infrastructures (CNII) to ensure that they are protected to the level commensurate with the risks they face”.

The policy is aware that the CNII is highly interdependent in nature and the goal of the policy is to establish a comprehensive program that will ensure effective cyber security controls throughout the country’s CNII. According to Jusoh (2016) these CNII assets include “those covering national economic strength, national image, national defence and security, the functioning of the Government and public health and safety”.

In order to combat cybercrime such as human trafficking using Information Communication Technology (ICT), the government of Malaysia amended the Computer Crimes Act 1997 effective as of June 1, 2000 by adding several offenses relating to the misuse of computers to the Act. More specifically, the Computer Crimes Act focuses on “unauthorized access to computer material, unauthorized access with intent to commit other offenses and unauthorized modification of computer contents and makes provisions to facilitate investigations for the enforcement of the Act”.

The Communications and Multimedia Act 1998, which came into effect on the April 1, 1999 “provides a regulatory framework to cater for the convergence of the telecommunications, broadcasting and computing industries, with the objective of making Malaysia a major global center and hub for communications and multimedia information and content services”. The Malaysian Communications and Multimedia Commission (MCMC) was appointed on November 1, 1998 as the sole regulator of the new

Table 3. Internet use, population data and facebook statistics for Malaysia

Population (2018 Est.)	Internet Users (Year 2000)	Internet Users (31 Dec 2017)	Penetration (% Population)	Users % Asia	Facebook 31 Dec 2017
32,042,458	3,700,000	25,084,255	78.3%	1.2%	22,000,000

Note. From “Internet Usage in Asia: Internet Users, Facebook Subscribers & Population Statistics for 35 countries and regions in Asia” by Internet World Stats. Retrieved December 1, 2018 from <https://www.internetworldstats.com/stats3.htm>

regulatory regime. Although regulation in the form of licensing is provided for, one of the cornerstones of the new regulatory framework is self-regulation by the various industries, including the internet and multimedia content industries. The Personal Data Protection Act (PDPA) 2010 was introduced to curb misuse of data to prevent criminal activities.

As discussed earlier in the article, the internet or deep web is alluring for cybercrimes and a vehicle for human trafficking. Moreover, it provides a convenient method for cybersex predators to indulge in their deviant behaviour. This draws attention to the actual number of internet users and the potential of becoming a victim to any form of sexual exploitation. That said, the usage of internet in 2017 for Malaysians age 15 and above was 80.1% (Department of Statistics Malaysia, 2018). This indicates that a tighter regulation of enforcement should be laid in place to curb human trafficking via ICT.

Table 3 shows Malaysia’s internet use, population data and Facebook statistics as of December 31, 2017 according to Internet World Stats.

According to Table 3 the internet penetration of Malaysia has risen by 78.3%, and with 22 million subscribers of Facebook as of December 31, 2017. The 2018 statistic was not available at the time of writing this article; however, at this rate, the statistics above show that there are more internet users in Malaysia and will continue to grow. Thus, Malaysia will need further protection from cyber criminals to feel safer while using their respective ICTs.

CYBERLAWS IN MALAYSIA TO COMBAT TRAFFICKING

Cybercrime is now more lucrative than drug trafficking and online users have the potential to be a cybercrime victim, and in most cases too, its perpetrators, with the younger generation as the most vulnerable targets. Technology is used to cheat, harass, disseminate false information and more than 70% of commercial crime cases in Malaysia are reported as cybercrime cases according to the Royal Malaysian Police (Rapid rise of cyber criminals, 2016, May 20). The existing cyber laws in Malaysia to combat human trafficking in the cyber realm are:

- Computer Crime Act 1997
- Communications and Multimedia Act 1998
- Malaysian Communications and Multimedia Commission (MCMC) Act 1998

However, the above mentioned legislations do not specifically mention human trafficking offenses per se. Instead, each of the Acts can combat human trafficking according to their purposes:

1. Computer Crimes Act 1997 was enacted to “provide for the offenses relating to the misuse of computers” More specifically, to combat human trafficking refer to Computer Crimes Act 1997 Section 4- Unauthorized access with intent to commit or facilitate commission of further offence,

which under Section 4(3) the offender is liable to a fine not exceeding RM150,000 or to imprisonment for a term not exceeding ten years or to both

2. Communications and Multimedia Act 1998 was enacted to:
 - a. To promote national policy objectives for the communications and multimedia industry;
 - b. To establish a licensing and regulatory framework in support of national policy objectives for the communications and multimedia industry;
3. Malaysian Communications and Multimedia Commission (MCMC) Act 1998 was enacted to establish MCMC to “regulate the communications and multimedia activities in Malaysia, and to enforce the communications and multimedia laws of Malaysia, and for related matters”

The current Malaysia legislations’ protection is insufficient to enforce human trafficking through internet. The above legislations provide only a general and broad definitions for prosecuting cyber crimes. The researcher suggest a specific definition for prosecuting “human trafficking” in the cyber laws.

MALAYSIA MULTI-LATERAL EFFORTS TO COMBAT TRAFFICKING

According to U.S. Government Accountability Office (GAO) Report (2018), the U.S. State Department developed international programs to assist countries to include Malaysia to combat trafficking. For instance, in fiscal year 2017, the State TIP Office Project “A cloud-based case data capture, management and analysis platform for anti-trafficking NGOs across Asian countries for standardization of TIP data collection and for data research. The countries involved Malaysia, Cambodia, Burma, Laos, Philippines, Thailand, Bangladesh, India, Nepal, Ghana, Kenya, and Uganda. The project began in October 2014 and ended in September 2018

A second project with State/TIP Office titled Enhancing National Counter-Trafficking Efforts in Malaysia started in January 2016 and ended in December 2017

In September 2015 to September 2019, U.S. Department of Labor/Bureau of International Labor Affairs/Office of Child Labor, Forced Labor and Human Trafficking had a project “From Protocol to Practice: A Bridge to Global Action on Forced Labor (The Bridge Project)” with global priority in Malaysia, Mauritania, Nepal, Niger and Peru; limited activities in Thailand, the Dominican Republic and Paraguay

It is clear that the U.S. and countries to include Malaysia are making efforts to combat human trafficking, however the crime is elusive and continues to be a global issue.

THE PALERMO PROTOCOL IN HUMAN TRAFFICKING

The Palermo Protocol adopted by United Nations on November 15, 2000 to supplement the U.N. Convention Against Transnational Organized Crime, does not take into regard of the possible difference of ‘cyber’ trafficking or ‘offline’ human trafficking, but rather defines human trafficking in article 3 as:

“recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation”

According to Witting (2017) to understand cyber trafficking is to determine whether or not the victim that remained in front of their computer is equally helpless and hence should be considered victims of human trafficking. Furthermore, Witting (2017) says that “many international tools point out that the element of movement is not necessarily required to constitute a human trafficking offense, citing as proof the term ‘harboring’ in article 3 of the Palermo Protocol”. However, in a case where a family member offers their child to strangers to be sexually exploited at home, the family in this case is ‘harboring’ the child for sexual exploitation, and this is considered human trafficking. This shows that the ‘harboring’ person must have received the victim from somewhere, and hence some sort of movement must have taken place earlier. This point has still not been formally addressed under the Anti-pemerdagangan Orang dan Anti-penyeludupan Migran (Malaysia Anti-Trafficking in Persons and Anti-Smuggling of Migrants Act 2007).

To remove a victim from their familiar environment is an integral element of trafficking. Witting (2017) says that:

“In order to facilitate the understanding that even the smallest movement is sufficient for trafficking, the attention was entirely shifted away from the aspect of movement; this simplification might have led to the misconception that no movement is required at all.”

The message that Witting (2017) points out is that “it’s not that a victim has been moved, but rather that the victim has been removed from his or her safe and familiar environment that is the key element in human trafficking.” Hence, this removing of a victim constitutes a form of movement.

FIGHT ONLINE SEX TRAFFICKING ACT (FOSTA) AND STOP ENABLING SEX TRAFFICKERS ACT (SESTA)

In February 2018, President Donald Trump of the United States signed into law “FOSTA” Fight Online Sex Trafficking Act and “SESTA” Stop Enabling Sex Traffickers Act to enable prevention of illegal sex trafficking online. The bills have been hailed by advocates as a victory for sex trafficking victims.

However, the bills have not resolved the “safe harbor” rule of the internet “Section 230 of the 1996 Communications Decency Act”. Section 230 states that “No provider or user of an interactive computer service shall be treated as the publisher or speaker of any information provided by another information content provider.” This means that under Section 230 it is permitting “the internet to thrive on user-generated content without holding platforms and ISPs responsible for whatever those users might create” (Romano, 2018, April 18).

But FOSTA-SESTA creates an exception to Section 230 whereby “website publishers would be responsible if third parties are found to be posting ads for prostitution including consensual sex work on their platforms”. The goal of this is supposed to police online prostitution rings easier. What FOSTA-SESTA has actually done, however, is create confusion and immediate repercussions among a range of internet sites as they grapple with the ruling’s sweeping language (Romano, 2018, April 18).

Malaysia is advised to foster or model FOSTA-SESTA; however, Malaysia Communication and Multimedia Commission currently has only Anti-trafficking in Persons and Smuggling of Migrants (ATIPSOM) 2017, Computer Crimes Act 1997, Commission Multimedia Act 1998 and the Penal Code to combat human trafficking.

RECOMMENDATIONS

Combatting human trafficking in the digital world is constantly evolving. Prevention efforts need to focus on the intersection of inter-government cooperation, cyber cops and technology.

The following recommendations are recommended to further combat human trafficking through the internet:

1. Online surveys on the use of technology to recruit, groom and sell domestic minor sex trafficking victims should be conducted. This will provide qualitative data on human trafficking.
2. Provide tools for law enforcement agencies in Malaysia and enforcement officers to be trained to handle human trafficking.
3. Government funds should be allotted for combating human trafficking efforts.
4. Advertisements against human trafficking should be placed on search engine results for pornography.
5. Further government collaboration is required for international, national and domestic law, NGO and accountability of internet usage.
6. Include specific definition for prosecuting “human trafficking” in the Malaysia cyber laws.

CONCLUSION

Human trafficking has evolved with the aid of technology, the internet and deep web. Traffickers are actively using the internet as a means to recruit, lure women and children into this heinous crime. Efforts to fight human trafficking as cybercrime are getting more challenging as the culprits are getting more innovative in dark web operations. The challenges of current cyber laws in Malaysia to combat human trafficking is to review the current cyber laws legislations and also to train the officers to handle human trafficking based on the proposed revised cyber laws on human trafficking.

KEY TERMS AND DEFINITIONS

Cyber Law: The legal system dealing with cyberspace and the internet.

Darknet: The hidden computer network typically used for illegal trading and forums to include illicit activities such as human trafficking.

Deep Web: The hidden part of the web invisible to conventional search engines.

Human Trafficking: Modern day slavery or illegal transporting of people typically for the purposes of forced labor or sexual exploitation.

Sexual Exploitation: Taking advantage of a person sexually for personal gain or make profit.

Smuggling of Migrants: The facilitating of illegal entry of a person into a country he or she is not a national or resident of.

Trafficking in Persons: Human trafficking or the recruitment, transfer, transportation, or harboring of people by coercion or force, abduction, fraud, deception.

Web-Based Child Sexual Exploitation

3

Lacey Nicole Wallace

Penn State Altoona, USA

INTRODUCTION

Use of technology including smartphones and social media is extremely common among youth. In a 2018 poll by the Pew Research Center, 85% of teens ages 13 to 17 reported that they used YouTube (Anderson & Jiang, 2018). In the same poll, 72% of teens reported using Instagram, 69% reported using Snapchat, 51% reported using Facebook, and 32% reported using Twitter. Use of web-based technology among juveniles increased sharply in recent years. In 2015, about three-quarters of teens had a smartphone or access to a smartphone (Lenhart, 2015). In 2018, more than 95% of teens had a smartphone or easy access to one (Anderson & Jiang, 2018). About 88% had access to a desktop or other form of home computer. Social media use has also evolved. In 2015, Facebook was the most common social media platform used by teens (Lenhart, 2015). In 2018, Snapchat became more popular among teens, though Facebook use remained more common among low-income youth (Anderson & Jiang, 2018). Teens today use a variety of social media and other web-based platforms to communicate, learn more about the world, and entertain themselves (Anderson & Jiang, 2018; Lenhart, 2015). Teens also spend a substantial portion of their time online. In 2018, 45% of teens reported that they were nearly constantly online (Anderson & Jiang, 2018). That figure was only 24% in 2015 (Lenhart, 2015).

Unfortunately, use of social media and other technologies can place teens and other juveniles at risk for sexual exploitation. One example is sexting, a trend that has grown in popularity among youth. Across 39 studies, an average of 15% of juveniles reported sending a sexually explicit text message to someone (Madigan, Ly, Rash, Ouytsel, & Temple, 2018). More than a quarter, 27%, reported receiving a sexually explicit text message. Once sent, juveniles risk having the sext forwarded to other juveniles or adults, or posted online, without their consent. Roughly 12% of juveniles reported forwarding sexts without consent (Madigan et al., 2018). In some cases, commonly termed revenge porn, the forwarded content is used to bully, embarrass, or intimidate the youth involved.

The web can also be used as a tool to engage in other forms of child sexual exploitation, such as child pornography or child prostitution. This chapter explores this topic with the following objectives:

- Define child sexual exploitation and its various web-based forms
- Detail the state, Federal, and international laws prohibiting child sexual exploitation
- Outline what is known about victims and offenders
- Describe current initiatives to prevent or detect web-based child sexual exploitation

Additionally, this chapter describes difficulties in prosecution and detection as well as areas where further investigation is needed.

DOI: 10.4018/978-1-5225-9715-5.ch036

DEFINING CHILD SEXUAL EXPLOITATION

The Federal Bureau of Investigation (FBI) defines the term exploitation as “the act of taking advantage of something; esp., the act of taking unjust advantage of another for one’s own benefit.” Since the definition is vague, many activities involving children (youth under age 18) can be classified as criminal exploitation, including sexual abuse and rape. Many examples in this chapter fall under the category of commercial sexual exploitation of children (CSEC). CSEC refers to sexual exploitation of children for either financial benefit or in exchange for items or services that hold a value of some sort. Examples of CSEC and other forms of child sexual exploitation that can be facilitated through the web include:

- Child pornography production and distribution
- Child prostitution
- Transporting children for the purpose of prostitution (also termed sex trafficking)
- Webcam child sex tourism (WCST)
- Online child sexual exploitation (OCSE)

These terms can be somewhat confusing since countries and other sources sometimes disagree on definitions. Additionally, some forms of CSEC can occur in person while others require no face-to-face contact.

Child Pornography

In the U.S., Federal law defines child pornography as “any visual depiction of sexually explicit conduct involving a minor.” (Department of Justice, 2015c) Child pornography can come in many forms including video, photographs, and computer-generated images designed to look like real children. While the phrase sexually explicit can refer to images of children engaged in sexual activity, that is not a requirement under the definition. Images that are sexually suggestive may also be considered child pornography. Unlike some of the other forms of exploitation, child pornography does not require face-to-face contact between the minor involved and the end-recipient (i.e. consumer). Given available technology, child pornography can easily be obtained and transferred on the web. One example is the increasing prevalence of P2P, or peer-to-peer networks, in the distribution of child pornography. P2P networks are computers connected to each other via the web, where files can be shared directly across computers without the need for a central server (Wolak, Finkelhor, & Mitchell, 2012).

An additional concern is that images later distributed as child pornography may not have been initially intended as such. Revenge porn refers to the use of sexually explicit images without someone’s consent, typically to embarrass, bully, or intimidate. When used to gain money, services, or other items, this behavior is referred to as sextortion. As one example, an adult man in Florida named Michael Chansler contacted at least 350 teenage girls across the U.S. and Canada between 2007 and 2010 and persuaded them to send him sexually explicit images (Greenberg, 2017). Later, he threatened to tell the girls’ parents if they did not continue to send him sexually explicit images. He was later convicted on child pornography charges.

Child Prostitution

The term prostitution refers to participation in any form of sexual activity for profit. In this case, profit can refer to financial gain or the exchange of sexual favors for services or physical goods. For adults, prostitution is illegal everywhere in the U.S. except for certain counties in Nevada (FindLaw, 2018). Even in those counties, however, there are strict restrictions on who can participate and where. Prostitution involving any individual under age 18 is illegal in all jurisdictions in the U.S.. While the term sexual activity may imply that face-to-face contact between a minor and an adult is necessary, attempting to solicit a minor for sexual activity over the internet is also considered a crime.

Child Sex Trafficking

The U.S. Department of Justice (2015b) defines child sex trafficking as “the recruitment, harboring, transportation, provision, obtaining, patronizing, or soliciting of a minor for the purpose of a commercial sex act.” In many instances, the terms prostitution and trafficking are used synonymously when referring to crimes involving children (Montgomery, 2010). Indeed, child prostitution is a form of child sex trafficking since patronizing and soliciting a minor for participation in sexual activity are both included in the definition of child sex trafficking. Yet, child sex trafficking is a broader category of offenses that include both crimes that take place in person as well as those that do not involve face-to-face contact. One example of the latter is webcam child sex tourism.

Webcam Child Sex Tourism (WCST)

Child sex tourism is defined as the “the commercial sexual exploitation of children by people who travel from one location to another and take part in sexual acts with children” (Kapell, 2009, p. 7). Given advances in technology over the past several decades, however, physical travel is no longer necessary for certain forms of this behavior. Webcam child sex tourism refers to adults who pay to watch children engage in sexual activities live via webcam (Acar, 2017). This behavior is also termed webcam child sexual abuse. In some cases, viewers can interact with the children involved and request that they perform specific actions. Often, the viewer and child are in different countries (Terre des hommes, 2018). However, this is not always the case.

Online Child Sexual Exploitation (OCSE)

Webcam child sex tourism is one form of a broad range of offenses termed online child sexual exploitation (OCSE) or online child sexual abuse. These terms refer to the use of information technology including social media, webcams, or cell phones to solicit or coerce children to engage in illegal or inappropriate sexual activity. Since no face-to-face contact is required, these behaviors often do not fit traditional definitions or understandings of child sex trafficking. Often, OCSE is preceded by a behavior known as grooming. Grooming refers to an offender’s efforts to gain a child’s trust and collect information about the child before making sexual advances (Kloess, Beech, & Harkins, 2014).

LAW

Many U.S. laws prohibit the sexual exploitation of children (Adams & Flynn, 2017). These include laws at the state and federal level as well as international agreements to which the U.S. is a party. The pages to follow review key Federal laws as well as examples of law and policy at the state and international level.

Federal

Child exploitation typically falls under Federal jurisdiction if the crime involved individuals in multiple states or countries, if the offense involved the internet, and in some cases where the materials or equipment used in the crime originated in a different state or country than where the crime occurred (Department of Justice, 2015c). At the Federal level, the law (USC § 2251) states that any individual who

employs, uses, persuades, induces, entices, or coerces any minor to engage in, or who has a minor assist any other person to engage in, or who transports any minor in or affecting interstate or foreign commerce, or in any Territory or Possession of the United States, with the intent that such minor engage in, any sexually explicit conduct for the purpose of producing any visual depiction of such conduct or for the purpose of transmitting a live visual depiction of such conduct (U.S. Government, 1978b)

is guilty of a criminal offense. In other words, this law makes the production of various forms of child pornography illegal. Those outside of the U.S. who commit these offenses are also criminally liable if they transport or intend to transport sexually explicit material involving minors to the U.S. (U.S. Government, 1978b). Transport can include web, phone, or other electronic transfer; it does not need to involve a person traveling to or from the U.S. Penalties for committing these offenses are severe and increase in severity for those who have previously committed crimes involving children. A first offense results in incarceration for 15 to 30 years, a second in a sentence of 25 to 50 years, and a third results in 35 years to life in prison (U.S. Government, 1978b). Additionally, individuals can be prosecuted for knowingly possessing or receiving sexually explicit images of children; both production and consumption of child pornography are illegal in the U.S. (U.S. Government, 1978a).

Federal law (18 USC §2251A) further prohibits buying, transferring custody, or selling children for the purpose of sexual activity (U.S. Government, 1988). Each of these actions is a form of child sex trafficking. As with child pornography production and distribution, penalties are quite severe. The sentence for a first offense is 30 years to life in prison, regardless of whether that person is found guilty of selling a child, taking custody of a child, or purchasing a child for sexual purposes. However, child sex trafficking can involve other activities that extend beyond buying and selling. Under Federal law (18 U.S. Code § 1591), any person who “recruits, entices, harbors, transports, provides, obtains, advertises, maintains, patronizes, or solicits” a person for the purpose of sexual activity is guilty of sex trafficking (U.S. Government, 2000). These behaviors can occur on- and off-line. Penalties for these activities are more severe if they involve children under 14, but also involve a sentence of imprisonment for 10 years or more (U.S. Government, 2000). In addition to the statutes noted above, sex trafficking for both children and adults is prohibited by the 2000 Trafficking Victims Protection Act, the 2015 Justice for Victims of Trafficking Act, and the 2014 Preventing Sex Trafficking and Strengthening Families Act (National Conference of State Legislatures, 2018).

State

3

While child trafficking, prostitution, and pornography prohibitions are also found at the state level, several states have passed additional laws to address child sexual exploitation. Safe Harbor laws are one example. These laws provide criminal immunity to juveniles who have committed criminal offenses as part of their exploitation. Juveniles involved in prostitution, for example, are committing a crime but may be exempt from criminal prosecution. Instead, the adult involved would be prosecuted. As of 2017, 20 states and the District of Columbia had such laws (National Conference of State Legislatures, 2017). There is significant variation in the specifics of these laws. North Dakota, Oklahoma, Kentucky, and Montana, for instance, require proof that a juvenile has been trafficked before the juvenile is eligible for criminal immunity. In Tennessee, criminal immunity is automatically applied if police determine that person involved in prostitution is under age 18. Some states only extend immunity for prostitution while others include additional crimes that may involve trafficking (National Conference of State Legislatures, 2017). Additionally, some states only extend immunity to those under age 16 (Newcombe, 2015).

Another state-level legislative initiative involves diverting youth who have been involved in child sex trafficking to programs and treatments outside of the juvenile justice system. These youth receive social services, counseling, housing assistance, and other aid as an alternative to juvenile justice processing. Generally, diversion is limited to first-time, non-violent offenders. As of 2017, 29 states and the District of Columbia had such efforts in place; 18 states and the District of Columbia offer both diversion and criminal immunity to juveniles involved in sex trafficking (National Conference of State Legislatures, 2017). In New York, as one example, a judge can convert a youth's charge to a person in need of supervision if the youth is 16-17 years old and enters a guilty plea. With this change, the youth is eligible for treatment and services rather than punitive sanctions. In Florida, youth believed to be sexually exploited can be classified as dependents and placed into short-term care facilities under the supervision of the Division of Children and Families (National Conference of State Legislatures, 2017).

While sexting may not be intended as exploitative in many cases, it is illegal in some states. Sexting is generally treated less harshly under the law than possession of child pornography, at least when it consists of images shared between minors. When an image is shared with an adult, child pornography prohibitions may apply. Some states also have laws prohibiting revenge porn. In Florida, for example, it is illegal for a person to

publish a sexually explicit image of a person that contains or conveys the personal identification information of the depicted person to an Internet website without the depicted person's consent, for no legitimate purpose, with the intent of causing substantial emotional distress to the depicted person. (Cyberbullying Research Center, 2018)

Georgia has a very similar statute.

One key legal challenge in comparing state laws and policies is that states differ in how they define the age of consent. Age of consent refers to the age at which a juvenile is believed to be capable of giving consent to engage in sexual activity. Sexual activity involving a youth below the age of consent is illegal. As of 2017, there were 31 states with an age of consent at 16 years old, 8 states where the age of consent was 17 years old, and 11 states where the age of consent was 18 years old (Howe, 2017). However, states vary in whether there are civil or criminal liabilities (or both) for offenders, as well as in whether there are exceptions for individuals who are close in age. Florida law, for example, has an exception for cases

where the juvenile is at least 14 and the offender is no more than four years older (Howe, 2017). Age of consent also varies by country, further complicating cross-national cases.

An additional difficulty in managing cases of web-based sexual exploitation is defining jurisdiction. Victim and offender may reside in different states or countries where laws regulating sexual offenses and age of consent vary. While the Federal government often handles cases like these that occur within the U.S., this is not always the case (Department of Justice, 2015c). Generally, an offense must be prosecuted in the same jurisdiction where it was committed. In practice, however, web crimes have been prosecuted based on where the crime initiated, where the crime continued, where the crime was completed, as well as the location where the impact of the crime was most apparent (Department of Justice, 2015a). Since some of these factors are difficult to determine with web-based crimes, the factors used to determine jurisdiction vary on a case-by-case basis.

INTERNATIONAL LAW AND POLICY

Unless worded otherwise, U.S. law typically does not apply to locations outside of the U.S. As a result, web-based crimes involving a U.S. victim and an offender in another nation may be exceptionally difficult to prosecute; the other nation in question would need to assist or cooperate with the U.S. Not all nations are willing or able to do so. While many nations have passed legislation criminalizing trafficking in persons, including offenses involving children, the number of investigations, prosecutions, and convictions for these crimes remains low in most countries. Generally, countries that have had legislation against human trafficking for a longer period of time, like the U.S., have more convictions for these crimes than countries where legislation is more recent (United Nations, 2016). There remain some countries that have yet to criminalize human trafficking. Several international efforts have focused on encouraging nations to adopt legislation that addresses child sexual exploitation and child trafficking more generally.

In 1996, representatives of 122 countries met in Stockholm, Sweden, to participate in the first World Congress Against Commercial Sexual Exploitation of Children (ECPAT International, 2013). At the time, the focus was on addressing commercial child sexual exploitation in Asia. Indeed, the Congress was first proposed by the non-profit organization End Child Prostitution in Asian Tourism (ECPAT) several years earlier. At the conclusion of the week-long Congress, the nations represented unanimously approved the adoption of an Agenda for Action (ECPAT International, 2013). Among other items, the Agenda stressed the need for cross-national partnerships, raising public awareness, and the development of laws criminalizing child sexual exploitation, whether occurring online or otherwise. While the Congress has been repeated twice since 1996, the agreements resulting from each Congress were non-binding, meaning nations could choose to uphold or disregard any recommendations at their discretion.

The recommendations of each Congress were based, at least loosely, on ideals contained in the United Nations Convention on the Rights of the Child (CRC), an international agreement approved by the United Nations in 1989. As of 2018, the United States remained the only country in the world that had not ratified the agreement. The CRC defines a child as any individual under that age of 18, but also notes that children may be defined as adults at an earlier age depending on a nation's laws. In a series of Articles, the CRC describes the civil, political, economic, health, and social needs and rights of children. The CRC, for example, prohibits capital punishment for children, states that children need to be protected from abuse and exploitation, and mandates that children have a right to be raised by their families (United Nations, 1989). Unlike the agreements resulting from the Congress described above, the CRC is legally binding and enforced by the Committee on the Rights of the Child. In 2000, two

Optional Protocols were added to the initial agreement. The second prohibits child prostitution, child pornography, and the sale of children (United Nations, 2000). As of 2018, this protocol had been ratified by 175 nations, including the U.S., and signed by 9 others. Like the overall CRC, each Optional Protocol is legally binding on nations that choose to ratify it.

VICTIMS AND OFFENDERS

Trends

The exact prevalence of web-based child sexual exploitation is unknown. Underreporting is common for sexual victimization in general. Children, specifically, may be further hampered by whether or not they understand that what has taken place is a crime, fear of punishment, or fear of the offender. Offenses are hard to detect, making tracking difficult even when reports are made. Offenses can occur using a variety of technologies and can involve individuals across multiple countries. Additionally, there is little consensus on the definition of online sexual exploitation.

Recent research in the U.S. found that unwanted online sexual solicitations, cases in which individuals made sexual comments or advances towards youth online, decreased among youth between 2000 and 2010. Across three national, self-report surveys, 19% of youth reported experiencing these sorts of requests in 2000 while only 9% experienced these unwanted communications in 2010 (Mitchell, Jones, Finkelhor, & Wolak, 2013). Additionally, youth became increasingly more likely to report to friends or others when these communications were received (Mitchell et al., 2013). Other research, however, found increases in reports of child sexual grooming, pointing to possible increases in web-based child exploitation (Kloess et al., 2014). Between 2004 and 2013, the number of individuals referred to Federal authorities for involvement in commercial sexual exploitation of children doubled (Adams & Flynn, 2017). Most of these cases involved child pornography. However, the percentages of cases detected through task forces also increased from 2006 to 2009, indicating that improvements in detection and reporting may be contributing to apparent increases (Wolak et al., 2012). As stated in the Introduction, there has been an increase in the percentage of teens who reported forwarding sexts without consent (Madigan et al., 2018). While many of these instances involve juveniles forwarding messages to one another, some cases involve adults.

Victims

Some children are more at risk for web-based sexual exploitation by adults than others. Those at greater risk include (Blue Ridge Thunder, 2018; Kloess et al., 2014; Villacampa & Gómez, 2017):

- Females
- Children 13 to 17 years old
- Children who feel lonely or isolated
- Victims of bullying or abuse
- LGBTQ youth
- Children seeking attention, love, or other forms of affection
- Children who are online frequently
- Children who post many personal details online or engage in other risky online behavior

Victim characteristics can vary by the specific type of exploitation considered and the country in question. The Internet Watch Foundation (IWF), for instance, conducted a study of live-streamed sexually explicit activities involving children, most distributed using webcams. Among the 2,082 images and videos identified, the youth involved most commonly appeared to be females between the ages of 11-13 (Internet Watch Foundation, 2018). These youth, however, differ from those who are solicited by adult offenders through social media or other means (Blue Ridge Thunder, 2018; Kloess et al., 2014; Villacampa & Gómez, 2017).

Offenders

Past research found that offenders of online child sexual exploitation held some characteristics in common (Villacampa & Gómez, 2017; Wolak, Evans, Nguyen, & Hines, 2013). They were more often:

- Male
- Non-Hispanic, White
- Individuals with psychological vulnerability: low self-esteem, loneliness
- Unmarried or not in a long-term relationship

Adults who target children online are generally not pedophiles and are typically non-violent (Kloess et al., 2014). Finkelhor's Precondition Model of child sexual abuse provides a useful way to understand why adults target children online (Howells, 1994). The model points to three pathways:

1. **Emotional Congruence:** The offender may feel they have more in common with children than adults
2. **Deviant Sexual Arousal:** For various reasons, the offender is sexually attracted to children
3. **Blockage:** The offender is unable to satisfy sexual or other needs with adults due to stressful or unusual life circumstances

Existing research identified three types of grooming used by adult offenders in cases that involve sexual abuse or exploitation of children (Craven, Brown, & Gilchrist, 2006). One is termed self-grooming and refers to an offender's efforts to justify and deny either their past behavior or actions they intend to take. The second refers to grooming environment and significant others. If an offender intends to meet the youth in person, for example, the offender may need to learn a parent's schedule or identify meeting places where detection is unlikely.

Grooming a child, the third form of grooming, involves identifying a vulnerable child (Craven et al., 2006). As described under Victims, youth targeted online may be victims of bullying or abuse, lonely, craving attention, or questioning their sexual identities (Blue Ridge Thunder, 2018; Kloess et al., 2014; Villacampa & Gómez, 2017). Youth may indicate their vulnerability by posting their thoughts online, reaching out to others for support, or simply by visiting certain websites or chatrooms. An offender can gain a child's trust online in many ways that include, but are not limited to: posing as a same-age peer, offering support or encouragement, complimenting or praising, discussing non-sexual topics first, discouraging contact with others, sharing "secrets," or making promises. With the exception of promises of love or romance, use of trickery and deception is uncommon. Past studies found that only about 5% of online offenders pretended to be teens when they approached victims online (Wolak, Finkelhor,

Mitchell, & Ybarra, 2008). It was also rare for offenders to hide their interest in sex. Most victims who met offenders in person expected sexual activity to occur.

SOLUTIONS AND RECOMMENDATIONS

In an effort to prevent child exploitation, the United Nations monitors child trafficking and other offenses. In 1990, the United Nations established the Special Rapporteur on the sale of children, child prostitution and child pornography. This group of independent human rights experts investigates violations worldwide and provides advice to the U.N. and specific nations on how to address and improve conditions for children. The Special Rapporteur conducts country visits (by invitation), provides annual reports to the U.N., reports violations to the governments of the nations involved, and works to raise awareness through the media, conference presentations, and other venues. The Special Rapporteur reports violations even to those countries that have not signed or ratified the Convention on the Rights of the Child or its Optional Protocols (United Nations, 1990). Unfortunately, convictions for child trafficking and related crimes have remained fairly stable in recent years, even though more countries have passed legislation prohibiting child sex trafficking and other forms of child sexual exploitation (United Nations, 2016). Thus, legislation alone does not seem to be enough to prevent child sexual exploitation.

Other organizations have developed creative solutions to address web-based child sexual exploitation more directly. Terre des Hommes, a non-profit based in the Netherlands, is one example. In 2013, the organization used a computer-generated girl named Sweetie to locate adults taking part in webcam child sex tourism. Sweetie, playing the role of a 10-year-old Filipino girl, had the ability to speak and interact with web users with the appearance of a real girl. Adult offenders, generally men, would approach Sweetie online and make sexual requests. Afterwards, Terre des Hommes reported the adult offenders to their home countries for potential prosecution. In 2013, more than a thousand adult offenders were identified through Sweetie within a two-month period. The non-profit is currently working on more advanced software, Sweetie 2.0, that countries can implement themselves to detect, investigate, and prosecute webcam child sex tourism (Terre des hommes, 2018).

It is not uncommon for local and state law enforcement agencies in the U.S. to use similar tactics to detect and respond to adults seeking out children online. Rather than use a computer-generated girl, many law enforcement agencies instead create social media profiles and other information online to develop a fictional persona of a child, typically female. When approached by adults online, officers posing as the child interact through chat, email, and text. By arranging to meet or through investigating personal information shared by the offender, adults attempting to exploit children can be apprehended. This approach is not without controversy or difficulty, however. In some countries, such as Singapore, the law requires that a real child be contacted in order for a case to be prosecuted. In the U.S., entrapment is a legal defense. If the defendant can show that police led them to commit a crime they would not otherwise have committed, the defendant may be able to avoid prosecution. Further, not all countries have laws against grooming (Urbas, 2010).

FUTURE RESEARCH DIRECTIONS

Additional research is needed to better understand web-based child sexual exploitation. The prevalence of these offenses is unknown. Existing sources of crime data often focus on one offense, like child pornography, but not others. Part of this difficulty stems from the lack of a consistent definition for what web-based child sexual exploitation entails. Unlike other crime types, these are offenses that are not reported through the FBI Uniform Crime Reports (UCR) program. Even if they were, the UCR only account for crimes reported to police; sexual victimization is frequently underreported. A common source of victimization data in the U.S., the National Crime Victimization Survey, includes respondents ages 12 and older. However, the survey does not enquire about web-based sexual exploitation. The Youth Internet Safety Survey, a national self-report survey of youth, has not been replicated since 2010 (Mitchell et al., 2013). As a result of these concerns, recent trends are unknown or, at the very least, unclear.

CONCLUSION

The term child sexual exploitation refers to a wide array of behaviors that occur on- and off-line. Extensive internet and technology use among teens and other juveniles creates many positive opportunities for education and social connections. However, it also provides a context in which exploitation can occur. Unfortunately, detecting and prosecuting web-based child sexual exploitation is very difficult. Laws differ substantially across states, the Federal government, and across nations. Some laws hold juveniles criminally liable for forms of exploitation that involve criminal activity by the juvenile, like child prostitution. Others provide leniency and offer reduced penalties for crimes like sexting that often involve youth. Few countries have yet to pass legislation prohibiting child sex trafficking and related offenses. However, those that have more recent legislation struggle to detect and prosecute cases that occur. Prosecution is further complicated by questions over jurisdiction and age of consent. Currently, little is known about the exact prevalence of web-based child sexual exploitation. Studies of victims and offenders largely rely on cases that were prosecuted through the courts, meaning they are not necessarily representative of all cases. Yet, several U.S. and worldwide initiative are attempting to prevent and address web-based child sexual exploitation. Some involve legislation. Others, however, are attempting to combat offending on the exact platforms where it occurs, using computer-generated children and live individuals posing as children. Further investigation is needed to assess the effectiveness of these efforts long-term, for both identifying offenders and prosecuting offenders.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

KEY TERMS AND DEFINITIONS

Child Pornography: Any visual depiction of sexually explicit conduct involving a minor.

Child Prostitution: A youth involved in sexual activity for profit, whether financial or otherwise.

Child Sex Tourism: The commercial sexual exploitation of children by people who travel from one location to another and take part in sexual acts with children.

Child Sex Trafficking: The recruitment, harboring, transportation, provision, obtaining, patronizing, or soliciting of a minor for the purpose of a commercial sex act.

Exploitation: Taking advantage of someone or something for personal gain.

Grooming: Attempts by an adult to build a child's trust and interest before making sexual advances.

Online Child Sexual Exploitation: Use of information technology including social media, webcams, or cell phones to solicit or coerce children to engage in illegal or inappropriate sexual activity.

Revenge Porn: Sexually explicit images sent or posted without a person's consent; often used to intimidate or embarrass.

Sexting: Sending or receiving a sexually explicit text message.

Sextortion: Use of a sexually explicit image or other sexually explicit material to coerce a person.

Using Luring Communication Theory to Analyze the Behavior of Online Sexual Offenders

INTRODUCTION

The prevalence of sexual offenders (SOs) contacting children online attempting to engage in sexual exploitation has increased dramatically in recent years likely due to more potential victims and greater offender anonymity in online environments (Davidson & Gottschalk, 2011; Hernandez, 2000). Since its inception in 1998, the National Center for Missing and Exploited Children has received nearly 28 million complaints submitted to their CyberTipline® concerning the online enticement of children for sexual acts with an increase of 150% within the first four months of 2016 (NCMEC, 2018). This startling statistic illustrates just how dangerous online environments are for children, and it underscores the pressing need to identify online SOs so they can be apprehended and prosecuted.

Online anonymity is an enabler for SOs. Suler (2004) described the effects of anonymity as instances of the *online disinhibition effect*, a phenomenon in which people say or do things via the Internet that they would not normally say or do in person. Three key factors involved in this process are *dissociative anonymity*, *dissociative imagination*, and *invisibility*. Dissociative anonymity is the ability for individuals to separate their online personae from their real identities (Suler, 2004). Dissociative imagination is the

DOI: 10.4018/978-1-5225-9715-5.ch037

tendency for people to create separate imaginary online personae, allowing them to avoid responsibility for what happens online because they believe it has nothing to do with offline reality (Suler, 2004). Finally, invisibility is the capability to stay hidden from others on the Internet, which is thought to give people the courage to do things they normally would not do (Suler, 2004).

The problem to be addressed in the present study was to examine the viability of a novel approach to the identification of online SOs despite their attempts to hide behind the curtain of anonymity. Specifically, we tested the hypothesis that Luring Communication Theory (LCT) may provide a useful way to understand and identify the steps SOs utilize in their efforts to exploit children using online communications.

BACKGROUND

Differences in the Etiology of Sexual Offending

Considerable past work has indicated that people become SOs in different ways and for different reasons. Building on the earlier work of Finkelhor and Araji (1986), who provided a comprehensive explanation for sexually deviant behavior, Hall and Hirschman (1991), Ward and Siegert (2002), and Middleton, Elliott, Mandeville-Norden, and Beech (2006) all have proposed models of sexual deviancy based on the influence of specific psychological and physiological contributing factors, such as cognitive distortions, difficulties with emotional regulation, personality problems, deviant triggers for sexual arousal, and intimacy deficits, all of which may lead to a distorted understanding of what defines appropriate sexual behavior, a condition sometimes referred to as having a *deviant sexual script*. According to these models, not all of the same contributing factors necessarily need to be present or even dominant for individuals to become SOs. This variability across individuals in the specific factors that can result in the emergence of sexual deviancy means that there are different etiologies, or experiential pathways, for becoming an SO. However, as noted by Middleton et al. (2006), when multiple factors are present simultaneously in an individual, they may develop the *pure pedophile* deviant sexual script in which there is a strong, if not exclusive, preference for children as sexual partners. These SOs gravitate toward online environments because of the greater number of potential victims and the aforementioned anonymity these situations provide (Davidson & Gottschalk, 2011; Suler, 2004).

A Motivational Dichotomy in Online Sexual Offending

The varied factors and pathways by which individuals become sexual offenders likely imply that not all *pure pedophiles* have the same exact deviant sexual scripts. An important study by Briggs, Simon, and Simonsen (2011) revealed two distinct behavioral patterns of online SOs based on an apparent difference in their motives for initiating contact with potential victims. In one pattern, offenders were motivated by the desire to arrange an in-person meeting in order to engage in an offline sexual relationship. These so-called *contact-driven* offenders engaged in a relatively short online relationship with few sexual behaviors because their focus appeared to be on meeting the child without delay (Briggs et al., 2011). In contrast, a second behavioral pattern was exhibited by offenders who were motivated to develop a purely online sexual relationship with their victims, engaging only in cybersex and exhibitionism. These so-called *fantasy-driven* offenders worked to maintain their online relationships for longer periods of time and were not interested in offline contact (Briggs et al., 2011).

Two recent studies provided further insight into the features that distinguish contact- and fantasy-offenders (Chiu et al., 2018; DeHart et al., 2016). Like the Briggs et al. (2011) study, these investigations found that the interactions between fantasy-offenders and their victims tended to be prolonged, often lasting for months; in comparison, contact offenders engaged in brief interactions sufficient to arrange a *hook up*. One reason that contact offenders kept their interactions short was because of concerns regarding the presence of a monitoring guardian who might terminate the contact or thwart the offender's goal of offline contact (Chiu et al., 2018). DeHart et al. (2016) also found that fantasy offenders were more likely than contact offenders to sexually expose themselves to victims by sending digital images. Additionally, nearly half of the fantasy offenders studied by DeHart et al. (2016) sought sexually explicit photos of their victims, whereas less than a quarter of contact offenders requested such images. Further, the study showed that many fantasy offenders would ask their victims about their genitalia and would often attempt to coach victims in methods of masturbation. In contrast, contact offenders sought to confirm the emotional immaturity of their victims in order to identify the viability of further interaction opportunities both online and in person (DeHart et al., 2016). Finally, Chiu et al. (2018) found that contact offenders oftentimes shared their experiences and emotions with their child victims, encouraging them, in turn, to open up. This strategy helped contact offenders build trust, which made in-person contact with their victims more viable.

Online Sexual Offending and a Luring Communication Process

Clearly, the exploitation goals of online sexual offenders depend on communication with their victims (Aslan, 2011; Black, Wollis, Woodworth, & Hancock, 2015; Whittle, Hamilton-Giachritsis, Beech, & Collings, 2013). A pioneering study reported by Olson, Daggs, Ellevold, and Rogers (2007) used published accounts of interactions between offenders and their victims to examine the communication processes offenders employed to entice their victims. The results of this study revealed a five-step communication process: Gaining Access, Developing Deceptive Trust (DDT), Grooming, Isolation, and Approach. This process, which Olson et al. (2007) referred to as *luring communication*, began with steps to obtain contact with a child-victim followed by multiple steps to engender a cycle of entrapment, luring the child into accepting online sexual advances.

As noted by Whittle et al. (2013), self-disclosure is essential for forging the relationship between offender and victim, and this process is a key part of each step in luring communication (Olson et al., 2007). Self-disclosure has implications for the nature of offender's use of DDT and Grooming, as potential victims will be more likely to disclose personal information if preceded by information about the offender (Chiu et al., 2018; Dindia, 2002). Additionally, Dindia (2002) found a causal relationship between the tendency of individuals to self-disclose and positive feelings toward them on the part of those to whom they disclose—self-disclosure increased positive feelings. By sharing information with and soliciting information from potential victims, SOs are thus able to generate a sense of trust and increase their likelihood of maintaining a relationship.

Elaboration of the LCT has involved adding sub-steps within several of the five major steps for the purpose of more accurately capturing the behavior of online SOs (Kontostathis et al., 2009). For example, within the second step, DDT, Kontostathis et al. (2009) added several sub-steps to better reflect the strategies they observed offenders using within this stage of chat communication. Olson et al. (2007) subdivided several of the later steps based on the analysis of the offender-child dialogues they examined. Considering the number of steps and sub-steps proposed to date (12), the LCT consists of

the comprehensive framework shown in Table 1 for understanding the strategies that SOs use when sexually engaging children.

Using Chat Dialogues to Differentiate Offenders and Victims

Most of the luring communications used by online SOs occur in the context of Internet chat rooms or text-based communications. Examination of these communications is a labor-intensive task that must be carefully carried out by Law Enforcement (LE) as part of identifying and prosecuting Internet predators. Researchers have had to devise ways to expedite the process of offender identification through after-the-fact examinations of chat dialogue transcripts using keyword searches and other text analysis strategies (Kajzer et al., 2018). Pendar (2007) used automatic text categorization techniques to discriminate between online SOs and pseudo-children, who were adult volunteers from Perverted Justice (PJ) posing as children online. Through the use of machine learning techniques focusing on specific word-level trigrams (any set of three words within a chat corpus), Pendar (2007) was able to distinguish between offenders and pseudo-children 94.3% of the time. Using a codebook and dictionary based on the steps in the LCT, Kontostathis (2009) and McGhee et al. (2011) conducted studies using a software application called ChatCoder to analyze chat transcripts via eight coding categories. The researchers were able to distinguish between predator and victim, using chat transcripts from PJ. A success rate of 60% correct identification was found suggesting that the LCT was a useful basis for developing offender identification algorithms that could be implemented in text-analysis software (Kontostathis, 2009). Kajzer et al. (2019) reported a greatly enhanced correct identification rate (>90%) both for offenders vs. victims as well as for offender types (contact vs. fantasy offenders) through the use of word-level models based on chat dialogue text.

Table 1. Luring communication Theory: Five main steps and corresponding sub-steps numbered in sequence from 1-12

Main Steps	Sub-steps				
<u>1. Gaining Access</u> Access to victims	No Sub-steps; only main step Gaining access to potential victims				
<u>Development of Deceptive Trust</u> Developing the relationship	<u>2. Activities</u> Non-sexual activities	<u>3. Compliments</u> Offering praise	<u>4. Personal Information</u> Personal details	<u>5. Relationship Details</u> History and attitude towards relationships	<u>6. Gifts</u> Offering or sending gifts
<u>Grooming</u> Preparing for sexual behavior	<u>7. Communicative Desensitization</u> Sexual language used to desensitize the child			<u>8. Reframing</u> Presenting sexual activity as positive and beneficial	
<u>Isolation</u> Isolation from support network	<u>9. Mental Isolation</u> Providing sympathy and support to the child			<u>10. Physical Isolation</u> Encouraging hiding of the relationship	
<u>Approach</u> In-person meeting	<u>11. Verbal Lead Ins</u> Request to meet for sexual activities			<u>12. Physical Contact</u> In-person meeting for sexual activities	

Note: The first step has no sub-steps

THE PRESENT STUDY

The present study represents a novel investigation in several important respects. First, this study considered all 12 steps and sub-steps of the LCT to classify offenders. Previous classification guided by the LCT has employed this theory on a more limited basis (Kontostathis et al., 2009; McGhee et al., 2011). Second, although several papers cite differences between contact- and fantasy-SO's (Chiu, et al., 2018; McCarthy, 2010; McManus, Almond, Cubbon, Boulton, & Mears, 2016; Merdian, et al., 2018), the present study is unique in its utilization of the LCT to further distinguish between the two offender types. Finally, past studies of online SOs have only been able to use transcripts from PJ. The current study utilizes PJ transcripts along with transcripts of chats between offenders and LE officers posing as children. The chat conversations of undercover LE officers are not generally available and, therefore, have not often been used in previously published research. Use of this data in this study will extend the present findings beyond the single source of chat data currently available to most researchers.

Based primarily on the differences between contact- and fantasy-driven SOs reported by Briggs et al. (2011), several predictions can be made about the outcomes of the present study with respect to luring communication. First, if contact-driven offenders are motivated primarily by the desire to make offline personal contact with potential victims, it follows that these predators should engage in more actions related to Physical Isolation (sub-step of Isolation), Verbal Lead-Ins, and Physical Contact (sub-steps of Approach) compared to fantasy-driven SOs. Second, if fantasy-driven offenders aim to fulfill their desires online, then they might engage in more luring communication behaviors related to developing and maintaining an online sexual relationship with the victim, particularly those involving Compliments (sub-step of DDT), Communicative Desensitization, and Reframing (sub-steps of Grooming) compared to contact-driven SOs. Finally, it could be expected that total number of chat sessions, along with the total length of the online contact, might favor fantasy-driven offenders who are not interested in offline relationships and who, therefore, may be motivated to maintain online contact for as long as possible.

Method

Participants

In this study, chat data was analyzed from two separate sources. First, transcripts of offenders who chatted with civilian vigilante volunteers posing as children online were acquired from the website Perverted Justice (www.perverted-justice.com; PJ). Second, chat data was also analyzed from offenders who had engaged online with undercover police officers posing as children obtained from the office of the St. Joseph County, IN, Prosecuting Attorney. From these sources, researchers randomly sampled and downloaded 33 transcripts from PJ (45%) and 40 transcripts from LE (55%) for a total of 73 transcripts. Each transcript contained a full record of the chat conversations between a single offender and a single pseudo-child.

The number of chat sessions for each offender ranged from one to 14 ($M = 3.32$, $SD = 2.94$). All 73 of the offenders (100%) were male. The offender ethnic makeup was comprised of 64 White (88%), four Hispanic (5.5%), four African American (5.5%), and one Asian (1%). Of these 73 offenders, eight had sexual screen names (11%), while 65 did not (89%). This data consisted of digital evidence from Internet crime investigations that were conducted between the dates of January 1, 2003 and December 31, 2008. All of the chats (100%) were done via Yahoo messenger. In the case of LE chats, the LE officer created a profile of a 13-year-old girl and entered a normal Yahoo chat room, such as "Indiana:1."

While in the chatroom, the officer would not actively engage in any conversation. Rather, an offender would see the pseudo-child enter the room and, if interested, initiate contact through Yahoo messenger.

Offender Classification

For each transcript, the offender was classified by human judges as either a contact-driven or a fantasy-driven offender. Experimenters had knowledge of the disposition of the investigation for the LE chats and knew if the offender had met the pseudo-child in person or had maintained a relationship solely on the computer. The validity of these classifications was checked independently by individual coders. At the completion of the coding process for each chat, an experimenter blind to the disposition classified the offender as either a contact-driven or a fantasy-driven offender. These classifications were then verified against the classifications determined from the disposition of the LE investigation. This verification process resulted in no discrepancies between the LE classifications and the coder classifications.

For the PJ chats, each transcript was initially read by two research assistants. Based on the content of the chat, the offender was classified as either a contact-driven or a fantasy-driven offender. Validity for these classifications was checked by comparing the classifications provided by the two experimenters. Throughout this process, there was 100% agreement. Overall, for both the LE chats and the PJ chats, 39 offenders (53%) were classified as contact-driven offenders and 34 offenders (47%) were classified as fantasy-driven offenders.

Procedure

Luring Communication Theory coding entailed categorizing every line of each transcript sent by the offender (each line was a separate communication or utterance in the messaging system) as belonging to one of the 12 sub-steps of the LCT process, or as being unrelated to any of the LCT categories. This coding was done by two separate coders, blind to each other's classifications. After both codings were completed, the separately coded transcripts were compared for purposes of reliability. The total number of ratings as well as the number of agreements and disagreements between coders were calculated, and inter-rater reliability was calculated using Cohen's Kappa. A Kappa of 0.60 is generally considered to be a moderate level of agreement (Cohen, 1960), and this value was used as the minimum threshold for inter-rater agreements in this study. For the 73 transcripts, Cohen's Kappa ranged from 0.61 to 0.98, with a mean inter-rater reliability of 0.83. These transcripts were then coded by an independent third rater who clarified any disparate codes between the first two coders.

After coding was complete, the original transcripts were examined to determine the number of offender utterances (lines) within each of the 12 sub-steps of the LCT, along with a total of the number of utterances (lines) unrelated to the LCT. This process was done by classifying each coded offender utterance with the number of the sub-step it coincided with (1-12). The total number of utterances made by the offender as well as the utterances that were not categorized into any of the sub-steps were also tallied. For verification, the total number of utterances in all 12 sub-steps as well as those in none of the sub-steps were combined to ensure that this sum equaled the total number of utterances tallied. This check confirmed that every offender utterance was classified as either being in one of the 12 steps of the LCT or not contained in a step. Once a count was obtained, a new variable was calculated that reflected the percentage of utterances made by the offender that were contained in each of the steps of the LCT. The resulting variable thus reflected the percentage of messages sent by an offender for each step of the LCT during the sexual solicitation of the pseudo-child.

Results

Data Exclusions and Analysis Plan

As noted above, each utterance (line) from an offender in each transcript was assigned a code based how the intent of the words in the line related to the steps/sub-steps of the LCT process shown in Table 1. Typically, lines that had relatively few words and/or were not expressing clear thoughts or intentions were coded as unrelated to the LCT. Since the purpose of this study was to examine how the LCT process related to offender communications, lines unrelated to the LCT were excluded from the analyses reported below. While lines unrelated to the LCT accounted for approximately 40% of the total offender *lines* across all chat transcripts, this percentage did not differ across offender types. Moreover, these non-LCT lines represented only a small percentage of the total *words* used by offenders in their communications (approximately 20% of total words). The effects of the independent variables in this study, Offender Type (contact- vs. fantasy-driven) and the LCT main step or sub-step, were assessed by means of mixed-factor ANOVA analyses using Offender Type as a between-subjects factor and the LCT main step or sub-step as a within-subjects factor. Effect sizes were computed as *r* values, where 0.1 is a small effect, 0.3 is a medium effect and 0.5 or above is a large effect (Cohen, 1988). Pooling PJ chats with those from LE was justified in this study by a preliminary analysis involving a Chat Source (PJ vs. LE) by Offender Type by LCT Steps/Sub-steps ANOVA that failed to reveal any significant main effects or interactions of these factors.

The Five Main Steps of LCT

Initially, researchers examined all codes subsumed by the five main steps of the LCT process shown in Table 1. Figure 1 depicts the percentage of offender conversation spent in each of these steps for both contact- and fantasy-driven offenders. It is clear that both types of SOs utilized the steps of DDT and Grooming much more than the steps of Gaining Access and Isolation in their conversations. Offender types differed markedly in their use of Grooming and Approach, but in opposite ways. That is, fantasy-driven offenders used the Grooming step more than contact-driven offenders, whereas the reverse was true for the Approach step.

To confirm these visual impressions, a 2 (Offender Type) X 5 (LCT Category) ANOVA was conducted on the percentage of conversation associated with each main LCT step. The analysis revealed a significant main effect of LCT Category, $F(4,71) = 115.24, p < .001, r = 0.79$, but no main effect of Offender Type. However, the interaction between Offender Type and LCT Category emerged significant, $F(1,71) = 20.86, p < .001, r = 0.47$. Follow-up, between-group tests revealed that the interaction occurred because fantasy-driven offenders engaged in significantly more Grooming, $t(71) = 3.65, p < .001, r = 0.40$, than contact-driven offenders, but significantly less Isolation, $t(71) = -2.69, p < .05, r = 0.30$, and Approach, $t(71) = -10.1, p < .001, r = 0.77$. Pairwise, within-group comparisons across steps within each offender type revealed that, for fantasy-driven offenders, DDT was significantly different from Grooming ($t(33) = 2.54, p < .05, r = 0.40$), and both of these steps were different from each of the remaining steps, all p 's $< .05$, which did not differ from one another. However, for contact-driven offenders, DDT, Grooming, and Approach did not differ, but each differed from both of the remaining steps, all p 's $< .05$.

Figure 1. Percentage of the conversation that contact-driven offenders and fantasy-driven offenders spent in each of the five main steps of the luring communication theory

LCT Sub-Steps

Development of Deceptive Trust

Sub-step comparisons were examined separately for main steps 2-5 (i.e. excluding Gaining Access which did not have sub-steps) starting with the five sub-steps of DDT. Examination of the mean percentage of conversation spent in each of these five sub-steps for each offender type revealed that Personal Information was the most prevalent sub-step used in this category by both offender types while Gifts was the sub-step least utilized. Use of each sub-step did not appear to differ by offender type. A 2 (Offender Type) X 5 (Sub-steps) ANOVA provided statistical confirmation of the impressions gained from examination of the means across the five sub-steps of DDT. The only effect to emerge significant from the analysis was the main effect of Sub-steps, $F(1,71) = 25.59, p < .001, r = 0.51$. Pairwise comparisons revealed that each sub-step was significantly different from all other sub-steps, all $ps < .05$, with the exception of Activities and Compliments, which did not differ from one another. Offender types did not differ for any sub-step.

Grooming

Figure 2 depicts the percentage of conversation spent in each of the two Grooming sub-steps. This figure shows that the first sub-step of Communicative Desensitization (sexual language used to desensitize the child-victim) was used more often during conversations than the second sub-step of Reframing by both offender types. However, fantasy-driven offenders used the first sub-step in this category markedly more than did contact-driven offenders, whereas the two offender types did not appear to differ in their use of the second sub-step. Confirming these visual impressions, a 2 (Offender Type) X 2 (Sub-steps) ANOVA revealed significant main effects of Offender Type, $F(1,71) = 13.34, p < .001, r = 0.40$, and Sub-steps, $F(1,71) = 183.23, p < .001, r = 0.85$, along with the interaction between Offender Type and Sub-steps, $F(1,71) = 15.92, p < .001, r = 0.43$. Follow-up comparisons revealed that the interaction

was due to a significant difference between Offender Type for Communicative Desensitization, $t(71) = 3.91, p < .001, r = 0.42$, but not for Reframing. Fantasy-driven offenders engaged in significantly more Communicative Desensitization than contact-driven offenders. Moreover, paired comparisons showed that both offender types used the first sub-step more than the second (fantasy-driven offenders, $t(33) = 10.27, p < .001, r = 0.87$; contact-driven offenders, $t(38) = 8.46, p < .001, r = 0.81$).

Isolation

Figure 3 depicts the percentage of conversation spent in each of the two Isolation sub-steps. This figure shows that contact-driven offenders used both sub-steps more often than fantasy-driven offenders. Moreover, the difference between offender types in their usage of Mental and Physical Isolation appeared roughly equivalent for both sub-steps. These observations were verified by a 2 (Offender Type) X 2 (Sub-steps) ANOVA showing only a significant main effect of Offender Type, $F(1,71) = 7.26, p < .05, r = 0.30$. Follow-up comparisons revealed that there were significant differences between Offender Types for Mental Isolation, $t(71) = 2.00, p < .05, r = 0.23$, and Physical Isolation, $t(71) = 2.57, p < .05, r = 0.29$. Contact-driven offenders engaged in significantly more Mental Isolation and Physical Isolation than did fantasy-driven offenders.

Figure 2. Percentage of the conversation that contact-driven offenders and fantasy-driven offenders spent in each of the two sub-steps of grooming

Approach

Examination of the mean percentage of conversation spent in each of the two Approach sub-steps revealed that the first sub-step of Verbal Lead-Ins (request to meet for sexual activities) was used more often by both Offender Types than the second sub-step of Physical Contact. However, contact-driven offenders used both of the sub-steps of Approach more often than fantasy-driven offenders. The 2 (Offender Type) X 2 (Sub-steps) ANOVA applied to these data revealed that both the main effects of Offender Type, $F(1,71) = 102.07, p < .001, r = 0.77$, and Sub-steps, $F(1,71) = 208.17, p < .001, r = 0.86$, were significant, as was the interaction between Offender Type and Sub-steps, $F(1,71) = 98.45, p < .001, r = 0.76$. The interaction occurred because the difference between contact-driven and fantasy-driven offenders was much larger for the use of Verbal Lead-Ins than for Physical Contact, but follow-up between group tests revealed that both differences were significant, $t(71) = 10.04, p < .001, r = 0.77$ and $t(71) = 5.81, p < .001, r = 0.57$, respectively. Contact-driven offenders used both Verbal Lead-Ins and Physical Contact significantly more than fantasy-driven offenders. Moreover, paired comparisons showed that both offender types used the first sub-step significantly more than the second (fantasy-driven offenders, $t(33) = 4.73, p < .001, r = 0.64$; contact-driven offenders, $t(38) = 14.57, p < .001, r = 0.92$).

Figure 3. Percentage of the conversation that contact-driven offenders and fantasy-driven offenders spent in each of the two sub-steps of isolation

Number and Duration of Chats

To assess the possibility of repeat conversations as well as the total time spent engaging with victims, number of chats sessions and chat durations per victim were determined for each offender type. This information was calculated from information contained within the transcripts, such as timestamps associated with each utterance. Independent sample t-tests were used to compare the total number of chat sessions as well as the total length of the chat conversations for contact- versus fantasy-driven offenders. No significant differences were found for either measure. The mean number of chats per offender was 3.32 while the average total chat length was 204 minutes.

Discussion

In this study, a novel approach was used to analyze communications between pseudo-children and child-sexual offenders using the Luring Communication Theory (Olson et al., 2007) as a basis for differentiating between the contact-driven and fantasy-driven offender types described by Briggs et al. (2011). Our approach revealed both similarities and differences between these two groups of offenders in their use of the LCT main steps and sub-steps as they were engaging in dialog with those that they believed to be children. Given that the LCT contained five main steps, four of which contained additional sub-steps, for ease of exposition our findings across all steps and sub-steps have been summarized in Table 2. The results shown in Table 2 can be viewed in the context of the three predicted outcomes of this study described earlier.

See Table 1 for LCT Step Definition

Prediction 1: Contact-driven offenders, who desire to make offline personal contact, should show more use of Physical Isolation (sub-step of Isolation), Verbal Lead-Ins, and Physical Contact (sub-steps of Approach).

The present results were consistent with the first prediction. When compared to the fantasy-driven offenders, contact-driven offenders were found to spend significantly more of their conversations engaged in the Physical Isolation sub-step of the main Isolation step as well as in both sub-steps of Approach step. The Approach sub-steps included Verbal Lead-Ins and Physical Contact. These findings support the idea that the overall goal of contact-driven offenders was to initiate offline contact, which can be facilitated through the use of Physical Isolation and the sub-steps of Approach. However, it was not anticipated that contact-driven offenders would also use Mental Isolation more than fantasy-driven offenders. Rather, it was expected that this tactic would be employed equally by both offender types as part of their persuasion tactics to maintain contact with the child-victim. But, Olson et al. (2007) noted that both of the sub-steps of Isolation involve distancing the victim from others in their lives, such as guardians, siblings, or peers, thereby increasing victim reliance on the offender. Therefore, it may be easier for a contact-driven offender to draw the victim into a physical encounter if the child does not have strong ties with others and instead places trust in the offender. This result is consistent with the finding of Chiu et al. (2018) that contact offenders are especially concerned about the presence of vigilant guardians and may thus explain why contact-driven offenders tend to engage in more overall Mental as well as Physical Isolation tactics than fantasy-driven offenders.

The present findings with respect to the sub-steps of Approach also are consistent with the different goals of contact- and fantasy-driven offenders as described by Briggs et al. (2011). Contact-driven offenders, who are thought to be focused primarily on initiating an offline relationship, engaged in significantly more Verbal Lead-Ins and Physical Contact strategies than fantasy-driven offenders. Both

Table 2. Summary of findings in main steps and sub-steps

Main Steps	Sub-steps					
<u>Gaining Access</u> <i>Findings:</i> Was least used step (< 3% of total offender communication) No difference between offender types here	<u>No Sub-steps; only main step</u> Gaining access to potential victims					
<u>Development of Deceptive Trust</u> <i>Findings:</i> Second most used main step (~19% of total communication) No difference between offender types here	<u>Activities</u> <i>Findings:</i> 2nd most used sub-step (<4% of total communication) No difference between offender types	<u>Compliments</u> <i>Findings:</i> 3rd most used sub-step (>3% of total communication) No difference between offender types	<u>Personal Information</u> <i>Findings:</i> Most used sub-step (>10% of total communication) No difference between offender types	<u>Relationship Details</u> <i>Findings:</i> 4th most used sub-step (~2% of total communication) No difference between offender types	<u>Gifts</u> <i>Findings:</i> Least used sub-step (<1% total communication) No difference between offender types	
<u>Grooming</u> <i>Findings:</i> Most used main step (>24% of total communications) Fantasy-driven offenders used this step more	<u>Communicative Desensitization</u> <i>Findings:</i> Most used sub-step (20% of total communication) Fantasy-driven offenders used this sub-step more			<u>Reframing</u> <i>Findings:</i> Second most used sub-step (~4% of total communication) No difference between offender types on this sub-step		
<u>Isolation</u> <i>Findings:</i> Second least used main step (~4% of total communication) Contact-driven offenders used this step more	<u>Mental Isolation</u> <i>Findings:</i> Sub-step accounting for approximately 2% of total communication Contact-driven offender used this sub-step more			<u>Physical Isolation</u> <i>Findings:</i> Sub-step accounting for approximately 2% of total communication Contact-driven offenders used this sub-step more		
<u>Approach</u> <i>Findings:</i> Third most used main step (~10% of total communications) Contact-driven offenders used this step more	<u>Verbal Lead Ins</u> <i>Findings:</i> Most used sub-step (~9% of total communication) Contact-driven offenders used this sub-step more			<u>Physical Contact</u> <i>Findings:</i> Second most used sub-step (~1% of total communication) Contact-driven offenders used this sub-step more		
<u>Chat Numbers/Durations</u> <i>Findings:</i> No difference between offender types						

of these sub-steps of Approach likely aid contact-driven offenders in their efforts ultimately to facilitate an in-person meeting with the victim. Since fantasy-driven SOs are only concerned with engaging in online sexual behaviors, they have less reason to engage in these Approach behaviors.

Prediction 2: Fantasy-driven offenders, who desire to maintain an online sexual relationship with the victim, should use more Compliments (sub-step of DDT), Communicative Desensitization, and Reframing (sub-steps of Grooming) than contact-driven offenders.

The findings of this study only partially supported the second prediction. While fantasy-driven SOs were found to use Communicative Desensitization significantly more than contact-driven offenders, these two types of SOs did not differ in their use of Compliments and Reframing. As anticipated, fantasy-driven offenders engaged in significantly more of the Communicative Desensitization sub-step

of Grooming than contact-driven offenders. Since these SOs are presumed to be more concerned with maintaining their online relationship with the victim, it is logical that they would employ Communicative Desensitization. This is a primary tactic by which fantasy offenders increase child receptiveness to sexual content (Lanning, 2010; Olson et al., 2007). Moreover, as Lanning (2010) has noted, Grooming is a *seduction* process that takes time to implement but ultimately facilitates ongoing access to the targeted child, a clear goal of fantasy-driven offenders. In contrast, contact-driven offenders were found in this study to be less likely to prolong the online relationship, consistent with their goals to move on to the steps of Isolation and Approach as quickly as possible in order to secure an in-person meeting with the victim, thus making them less likely to focus on desensitization efforts. In terms of using Compliments and Reframing, while it was thought these strategies might be especially important to the development of an ongoing online relationship for fantasy-driven offenders, in retrospect it makes sense that both types of SOs would make use of both strategies. Compliments help to strengthen relationships with victims, while reframing helps SOs present sexual behavior in a positive light and to normalize the behavior. Both strategies enable SOs to facilitate their deviant interests with victims.

Prediction 3: Fantasy-driven offenders, who are motivated to maintain online contact for as long as possible, would be expected to have a greater number of longer chat sessions than contact-driven offenders, who want to move offline as quickly as possible.

Contrary to this third prediction, it was found that both groups of SOs were similar in the number of chat sessions per victim in which they engaged as well as in the average duration of their chat conversations. Interestingly, neither type of offender dominated the online chats with their victims. Offender utterances accounted for 51% of the conversation while pseudo-children utterances occupied the remaining 49% of the conversation. Given that the presumed goal of fantasy-driven offenders was to cultivate and maintain an online relationship with victims (Briggs et al., 2011), it is not clear why more repeat conversations and/or longer chats did not characterize this offender type in this study, as was found in previous studies (Briggs et al., 2011; Chiu et al., 2018; Dehart et al., 2016). A notable difference between the present study and previous studies using pseudo-children (Briggs et al., 2011; Dehart et al., 2016), however, is the addition of LE pseudo-children. LE pseudo-children may be less likely than PJ vigilante volunteers to take steps to prolong and repeat chat sessions given the focus of LE on prosecutable cases. Also, the present study differed from that of Chiu et al. (2018) who used real children. Future research will be needed to determine the impact of these differences.

SOLUTIONS AND RECOMMENDATIONS

The present results have several important implications for the identification of online SOs. First, the outcomes of this study make a novel contribution to the understanding of the LCT described by Olson et al. (2007), as well as to the classification of offender types proposed by Briggs et al. (2011). This study demonstrates that contact- and fantasy-driven offenders do employ different aspects of luring communication in their online sexual exploitation of victims they believe are children. These outcomes reinforce the utility of the LCT as a general theoretical model for understanding the online communications between the SO and child-victim and underscore the importance of the motivational distinction between offender types proposed by Briggs et al. (2011).

Moreover, these findings expand on earlier work (Kontostathis et al., 2009; McGhee et al., 2011) showing that the LCT steps can be used as a basis for classifying offender versus victim based on chat behavior. While the present study was focused only on offender chats, it does show that the LCT model

is indeed quite relevant to an understanding of SO communications as suggested by Kontostathis et al. (2009) and McGhee et al. (2011). Although Kontostathis et al. (2009) and McGhee et al. (2011) developed coding schemes based on the LCT, they did not differentiate between contact- and fantasy-driven offenders in their populations. Accordingly, their classification accuracy may have been reduced because, as discovered in the present study, the LCT steps are not used equally overall by both offender types. If these researchers had a mixture of offender types in their populations, then variance in the LCT usage attributable to contact- and fantasy-driven offenders may well have influenced their classification accuracy outcomes.

Stemming from previous classification research, a broader implication of the present work is that a much greater predictive power can be achieved in SO classification processes by incorporating knowledge of how the LCT steps are used by these two offender types. The findings of this study strongly suggest that high levels of Communication Desensitization usage likely is indicative of communications from fantasy-driven offenders, whereas high levels of Mental and Physical Isolation, along with Verbal Lead-Ins, likely signifies communications from contact-driven SOs. These types of observations represent a finer-grained diagnostic tool for differentiating offender types, which ultimately may assist in better educating victims and their caregivers about the potential dangers of the Internet. In addition, enhanced predictive power can move the field closer to automating offender identification through the development of software capable of making real-time predictions about the motives of those engaging in sexually explicit chats with children; saving law enforcement agencies time and resources. Most importantly, the results of this study may facilitate efforts to identify online SOs so they can be taken offline and put out of contact with potential victims.

FUTURE RESEARCH DIRECTIONS

Several lines of further research are needed to better understand the present findings and address the limitations of this research. First, although both PJ chats and chats between online SOs and LE officials posing as children were utilized, researchers did not have access to any chats involving online SOs and real children. As such, it is as yet unknown if these results will generalize to online victims other than pseudo-children. Second, the coding scheme used in this research resulted in a large category of offender utterances unrelated to LCT (around 40% of total offender coded lines). As noted above, these utterances represented individual segments of the offenders' conversations that either involved few words, symbols, or abbreviations. In contrast, the LCT codes represented larger individual segments of offender conversations with many more words, symbols, or abbreviations per segment. Thus, in terms of words, the LCT-related codes encompassed about 80% of the offenders' portions of the conversations in the present study. Codes unrelated to the LCT were not parsed carefully in the present study, but should be more closely examined in future work. Third, the Pew Research Center reports that current trends of communication are shifted towards an increased use of SMS messaging and social media on mobile phones versus online instant messaging (Lenhart, 2012). While, it is not clear how this trend would change the nature of SO-victim conversations, this is an issue that needs to be explored in future research. Finally, as noted by many researchers (Aslan, 2011; Kirwan & Power, 2013; Kloess, Beech, & Harkins, 2014; Seto, Wood, Babchishin, & Flynn, 2012), more work is needed to better understand why individuals become online SOs. As this work unfolds, it may inform the process of identifying more specific types of online offenders. Although the present work was guided primarily by the classification of offenders proposed by Briggs et al. (2011), other types of offenders may exist, as suggested by several authors (Aslan, 2011;

Babchishin, Hanson, & VanZuylen, 2015; Kontostathis et al., 2009). If so, it will be important to see how any additional offender types may be similar or different in their use of luring communications.

CONCLUSION

The present study was the first of its kind to investigate the differences between contact- and fantasy-driven offenders using the LCT framework to learn more about their specific motives and behaviors. Clear differences were revealed in how these offender types used luring communications to exploit child victims based on their distinct contact or fantasy motives. Further research in this area is needed, but if this finding proves to be robust, it will provide yet another important way for law enforcement to differentiate these offender types based on samples of their communications with potential victims. However, as noted in several studies (Babchishin et al., 2015; Chiu et al., 2018; Long, Alison, & McManus, 2013; McCarthy, 2010; Merdian et al., 2018), contact- and fantasy-driven SOs may differ in other ways that also will be important to understand, both from the standpoint of identifying these offender types and bringing them to justice. Moreover, as indicated by Hillman, Hooper, and Choo (2014), various significant challenges also will need to be addressed related to the prosecution and remediation of SO's once they are identified and apprehended.

ACKNOWLEDGMENT

The authors wish to thank Nicholas Battis, Natalie Behrens, and the St. Joseph County Prosecutor, Ken Cotter, for their help with project.

KEY TERMS AND DEFINITIONS

Approach: LCT step used more by contact-driven offenders to facilitate in-person meeting.

Contact-Driven Offender: Online sexual offenders who seek face-to-face contact with their child victims to engage in physical sexual activity (Briggs et al., 2011).

Fantasy-Driven Offender: Online sexual offenders who seek only online interactions with children; often marked by illicit messages, exhibitionism, and child pornography (Briggs et al., 2011).

Grooming: LCT Step used more by fantasy-driven offenders to preparing for sexual behavior.

Isolation: LCT step used more by contact-driven offenders to separate victim from support network.

Perverved Justice: A grass-roots vigilante organization where volunteers pose as children online in order to expose offenders.

Pseudo-Child: A law enforcement officer or a volunteer posing as a child in a chatroom.

ICTs and Sexual Exploitation of Children in Europe

3

László Dornfeld

Ferenc Mádl Institute of Comparative Law, Hungary

INTRODUCTION

‘Child pornography’ is a negative social phenomenon directed against children who are a more vulnerable group of society due to their age, as they are still undergoing intellectual and moral development. It is also a global phenomenon just like cybercrime where the created material can be distributed anywhere in the world.

- With the advance of information technology, new methods of creating, acquiring and distributing child sexual exploitation material have begun to surface. The newest manifestation of this trend is the emergence of the so-called ‘virtual pornography’.
- The technology is relatively cheap, easy to access and portable. It allows for storage of large amounts of material, which would be conspicuous if stored in hard copy.
- Cyberspace provides an inexpensive and anonymous arena for offering, procuring, distributing, transmitting and sharing indecent pictures and videos, and represents an easy and very cheap way to access or obtain child pornography.
- As a result of advances in digital technology and the proliferation of information and communication technologies (ICTs), new forms of crime have emerged, many of which, like “outing and trickery sharing”, “repeated cyberstalking” or “snuff videos”, may overlap with child pornography offenses (Váradi-Csema, 2013, pp. 14-16).

The aim of this chapter is to outline the characteristics of child pornography, including the proper definition of the phenomenon. Then the next chapter discusses how ICTs transformed the production and distribution of child pornographic materials and how modern technology can help in covering the tracks of perpetrators. The chapter also addresses the new phenomenon of ‘virtual child pornography’. The last chapter is about the EU’s response to these criminal behaviors and new developments. The chapter mainly focuses on addressing European answers and regional level supranational legislation. National regulations may appear as examples in the text but not in-depth, taking the limited space of this chapter into consideration.

BACKGROUND

With each technological advance, the availability of child pornography was increasing, the latest being the Internet and ICTs (Quayle, 2011, p. 343). The origins of the development of child pornography can be traced back to the 1960s (Astinova, 2013, p. 4). Throughout these years, there was a gradual relaxation of laws regarding pornography (Gillespie, 2016, p. 227). For example, for almost a decade, all porno-

DOI: 10.4018/978-1-5225-9715-5.ch038

graphic materials were decriminalized in some North European countries, as there was only concern for the consumer and not for the circumstances of the production of these materials. Anti-pornography laws were repelled in 1969 in Denmark and in 1971 in Sweden (Quayle, 2011, p.343). The availability and distribution of child pornography through the Internet has become a social concern for society since the mid-1990s (Akdeniz, 2008, p. 1) The number of prosecutions in the UK involving indecent photographs of children increased from 93 in 1994 to 1,890 in 2003 (Clough, 2010, p. 248).

Sometimes it is questioned whether it is necessary to criminalize child pornography. Astinova argues that it has a preventive function because the demand for such materials provokes further child abuse and exploitation (Astinova, 2013, 4). In Gillespie's opinion, the harm caused to children is the primary reason, while later victimization due to the spread of such material is the secondary reason (Gillespie, 2016, p. 228). The question arises from these opinions: what about those materials which were produced without any victims (digital images, drawings or willing contributors)? This will be addressed later in the chapter.

Child pornography has changed drastically, industrial and technological advances have affected availability, photography, printing and distribution online (Taylor & Quayle, 2003; Aiken, Moran & Berry, 2011). As these materials can be accessed globally through the Internet, an international response is required, especially because of the jurisdictional challenges it raises (Gillespie, 2016, p. 231). In order to fight child pornography, different initiatives were adopted by the international and regional organizations such as the United Nations, the Council of Europe and the European Union (Herczeg, 2014, p. 70).

CHARACTERISTICS OF CHILD PORNOGRAPHY

The following chapters are focusing heavily on the regulations in various international and supranational instruments. Their territorial scopes differ significantly, as one is a global instrument while two were adopted by the Council of Europe (CoE) and thus include countries outside of the Europe Union and one is an EU Directive exclusively for Member States to observe. This means that the confusing situation caused by the already conflicting provisions is much worse.

- Optional Protocol to the Convention on the Rights of the Child on the sale of children, child prostitution and child pornography (United Nations General Assembly Resolution A/RES/54/263 of 25 May 2000; 'OPSC')
- Convention on Cybercrime (Council of Europe, ETS No. 185 of 23 November 2001; 'Budapest Convention')
- Convention on the Protection of Children against Sexual Exploitation and Sexual Abuse (Council of Europe, CETS No. 201 of 25 October 2007; 'Lanzarote Convention')
- EU Directive 2011/93 on combating the sexual abuse and sexual exploitation of children and child pornography ('Directive 2011/93')

The UN's OPSC, an optional protocol to the Convention on the Rights of Child ('CRS'), although drafted in the digital age, pays little attention to the ICT-based abuse of children (Gillespie, 2016, p. 231). The CoE drafted the Budapest Convention as the first international treaty seeking to address Internet and computer crime by harmonizing national laws. As of the end of 2018, more than sixty countries joined the convention ('Council of Europe', 2018) which has a wide range of topics, focusing on both criminal law and criminal procedural law issues. It should not come as a surprise that child sexual exploitation only constitutes a small proportion of the content of the Convention and the only offense it covers is

child pornography (Art. 9). As this was widely criticized, the Lanzarote Convention was adopted by the CoE to tackle all forms of child sexual exploitation (Gillespie, 2016, pp. 231-232).

The European Union had the Framework Decision 2004/68/JHA drafted as part of the ‘third pillar’ to combat child pornography on Union level but it was largely ineffective due to the limitations of EU’s competence in criminal matters. After the Treaty of Lisbon came into effect in 2009, providing a clear mandate to deal with computer crime offenses, the EU has begun to rethink the existing legal regime on both policy and legal level (Buono, 2012, pp. 342-343). As a result of this process, the Directive 2011/93 was drafted, which is legally binding, meaning it is directly enforceable. Thus, it can be considered the “strongest” among the legal instruments.

Terminology

Sexual exploitation of children is a term for a wide range of sexual crimes involving children, like child prostitution or sex tourism. The most important aspect of the term in a digital environment is the creation and distribution of illegal material depicting sexual acts involving children. The proper terminology for describing this phenomenon is much disputed. ‘Child pornography’ is still widely used in legal documents while there is an emerging trend to replace it with other terms, including ‘child sexual abuse material’. The reasoning behind this is that many find the word ‘pornography’ misleading, as it suggests mutual consent, some even going as far as stating that this wording “glorifies” the abusive content (Akdeniz, 2008, p. 11). The Virtual Global Taskforce states that labeling abusive material as ‘pornography’ legitimizes it and distances it from its criminal nature (Mathew, 2009). Some argue that the current terminology “creates a false distinction between the viewing of images and the contact sexual abuse of a child” (“PartnerSPEAK”, 2015).

The European Parliament, in its Resolution on Child Sexual Abuse Online of 11 March 2015, stated that in the future ‘child sexual abuse material’ should be adopted as the correct terminology (2015/2564(RSP), Para. 12). The Terminology Guidelines drafted on 28 January 2016 by the Interagency Working Group on Sexual Exploitation of Children (‘Luxembourg Guidelines’) takes the middle ground and concludes that ‘child pornography’ is still used in legal documents but should be avoided outside of legal context (Greijer & Doek, 2016, p. 38).

This reasoning however is a bit too academic in nature as end material is tied so close to the act of abusing children that it is hard to believe society would become more accepting of the phenomenon just because of the terminology. Yes, some individuals or advocacy groups (like the infamous North American Man/Boy Lovers Association) might try to use it as a justification. There are also people who think positively of online piracy as they see it as a form of freedom from big corporations and there are even Pirate Parties in some national legislations but they rarely advocate for actual Somali pirates. A closer example would be the emergence of the term ‘revenge porn’, the disclosure of private sexual photographs or films, which also constitutes a criminal offense and so far, no one labeled it problematic or glorifying.

Moreover, the proposed replacement terms can also be misleading. For example, ‘abuse’ implicates that children must be harmed while making these materials, which is simply not true given recent developments, like virtual child pornography. In addition, it fails to take into consideration the increasing trend of children willingly producing these materials (Gillespie, 2012, pp. 3-4), as sexually active teenagers with a profound knowledge of ICTs are more likely to do so. This topic will be further explained in a later subtitle of the chapter. Although better solutions, as ‘child exploitative material’ can be coined (Gillespie, 2012, p. 4), the widely used ‘child pornography’ is still the most accurate term, so it will be used throughout the chapter.

Definition of Child Pornography

There are numerous different definitions of the notion in various international, supranational and national legal documents. The scope of differences varies from the use of proper terms to the materials included and methods of committing the crime. Three different factors must be taken into consideration when determining which materials can be considered child pornography. These are:

- Age of the person
- Type of the material
- Nature of the material

The first criterion refers to the person involved in the explicit material, more simply the age requirement to be considered a 'child'. The UN's CRS clearly states that all persons under the age of eighteen shall be protected (Art. 1), which provision also applies to its optional protocol, the OPSC. The CoE's Lanzarote Convention and Budapest Convention also extend protection to anyone under the age of eighteen but the latter also gives the opportunity for signatories to lower the age-limit to sixteen (Art. 9 para. 3). Lastly, the Directive 2011/93 defines 'child' as any person below the age of 18 years. On a policy-making level, this solution is the easiest to implement as people above this age are considered adults capable of consenting to be depicted in pornographic material. Deciding based on physical appearance (bodily developments associated with puberty) and psychological aspects could be a problematic task for law enforcement, as only a few victims are identified even today despite the great effort on the authorities' part, so deciding based on age can be considered the most appropriate method (Gillespie, 2016, pp. 233-235). Although there may be minors psychologically mature enough to give consent and fully understand the consequences of being filmed, ultimately only the person who creates the material will be in the position to know the circumstances of the production (Gillespie, 2010, p. 205).

The biggest problem of age-based approach is the difference in age requirement between having consensual sexual intercourse and recording the act – even between spouses as the marriageable age is lower than 18 in some Member States. The age of consent differs from country to country: in Spain, it is 13 years, 14 years in Hungary (12 if both parties are minors), 15 years in the Czech Republic and 16 years in Belgium (Astinova, 2013, p. 11). The main reasoning behind this is the different consequences of having consensual sex and recording it, as the latter can be harmful to society and can boost the child pornography market (Clough, 2010, p. 257). In addition, it can be harmful for the individual too, as the recording can be posted on the Internet which later can yield search results when, for example, an employer is considering hiring the person. It can be argued that a sixteen-year-old is not ready to make such a decision and it was constantly done so by NGOs (Gillespie, 2012).

The second criterion concerns the type of material. Although we often associate pornography with visually depicting sexual acts, apparently there are other forms of it, like written texts and audio depictions. The international OPSC's scale is the widest as it states 'any representation, by whatever means' although most countries never criminalized all forms (Gillespie, 2016, p. 235). The other three instruments only consider the visual depictions of child sexual exploitation as child pornography. It is a logical choice if the justification for criminalization is based on the harm caused to children as it may cause secondary victimization through the later circulation of images (Taylor-Quayle, 2003, p. 194). Child pornography is not restricted to visual depiction but also can include text and audio depictions. Audio depictions can be just as harmful to children as images as these can be a recording of the sexual abuse of real children. Although it is not a common form of child pornography material, offenders may still find it sexually

arousing (Gillespie, 2010, p. 214). Text-based material is the most problematic since if it does not include identifiable children it is much more in the ‘fantasy’ realm. The fact that these may have artistic value must be also considered, for example, Vladimir Nabokov’s universally acclaimed novel *Lolita*.

Lastly, the nature of the material is to be addressed. There is a wide range of material from pictures that seem harmless in other contexts (e.g. catalog pictures of minors) to hardcore pornography. The UN Special Rapporteur in his report made a distinction between ‘hardcore’, ‘softcore’ and ‘erotic’ material. (Petit, 2004, p. 7-8) However, not all images will be subject to criminal law and thus there is a different categorization:

- Indicative: clothed children, implying a sexual interest in them,
- Indecent: naked children, implying a sexual interest in them,
- Obscene: children in explicit sexual acts.

Traditionally only the obscene images were punishable by criminal law (Gillespie, 2010, p. 206). In 2002, the University College Cork created the COPINE scale, which is a ten-point scale and it is used to categorize the level of seriousness of material with the aim to facilitate law enforcement cooperation (Astinova, 2013, p. 7). Three of the four international instruments (OPSC, Lanzarote Convention, Directive 2011/93) define the nature of the material as “a child engaged in real or simulated sexually explicit conduct or any depiction of a child’s sexual organs for primarily sexual purposes” while the Budapest Convention only contains the child engaging in sexually explicit conduct. The biggest problem with ‘child erotica’ (e.g. sexualized images of children in which the genitalia is covered) is that these can be freely disseminated and can undermine the effort to combat the sexual exploitation of children as a cover-up (Greijer & Doek, 2016, p. 42).

ICTS AND THE CHANGING PATTERNS OF CHILD PORNOGRAPHY

The use of ICTs changes the existing methods of creating and distributing child pornography. The ability to produce child pornography is greatly enhanced as digital images can be produced relatively cheaply without the need for external processing and reproduced with no diminution of quality. Cyberspace offers the opportunity to distribute the materials in large volumes, with minimal cost and relative anonymity (Clough, 2010, p. 249).

Virtual Child Pornography

As the production, possession, and distribution of child pornography is a serious offense in most countries, the perpetrators always try out new ways so that their activity falls into a gray zone of legality, which lowers the likeliness of persecution. It is much easier now, as technology has advanced to the point where a realistic depiction of a child can be created without a real child being involved (Gillespie, 2010, p. 211). The term ‘virtual child pornography’ in a wider sense refers to child pornography in cyberspace (including those with real children involved) while in a narrower, and more commonly used, sense it is pornography directly linked to cyberspace as it can only be produced in cyberspace (Poborilova, 2011, p. 242). There are three principal ways of creating virtual child pornography: 1) manipulating existing images (pseudo-photography) 2) computer-generating new images 3) dressing up adults as if they were minors (Gillespie, 2010, pp. 211-212).

Some authors use ‘pseudo-photography’ and virtual child pornography interchangeably (Gillespie, 2016, p. 245) but the latter term is wider and can include other forms of media like cartoons, manga, anime, etc. Pseudo-photography is created by digitally altering images, ‘blending’ or ‘morphing’ several together, for example putting a children’s face on an adult’s body to make it appear as if it is a child who is engaged in sexual activities (Greijer & Doek, 2016, p.41).

The main distinction Gillespie makes is that some images are only computer-manipulated while others are computer-created. Manipulating images can result in a new photograph that never actually took place (Gillespie, 2016, 245-246). Now even videos can be easily manipulated by the use of Deepfake, a technique for human image synthesis based on artificial intelligence, creating false images in only a few hours (Harris, 2019, p. 100). This can be utilized to produce child pornography and can be considered virtual child pornography. Computer-created images are fully generated by a computer and are not derivatives of photographs. It also must be noted that despite the rapid development of technology it appears that for the foreseeable future child pornography is likely to be created using real children (Clough, 2010, p. 272).

The main principle of virtual child pornography is that there is no abuse or other exploitation of a real child. As there are no children harmed during the production of these materials, the justification for criminalization must be on a different basis (Poborilova, 2011, p. 245). There are voices that claim private thoughts of an individual are part of the freedom of speech and criminalizing it would harm this principle (Gillespie, 2010, p. 213). The UK has put forward three principal justifications for criminalizing virtual child pornography: 1) it reinforces negative views toward children 2) it can be used for grooming children 3) it is frequently found alongside traditional child pornography. These justifications are rather weak: feeling in itself is rarely enough to justify criminalization (as freedom of speech extends to unpopular or offending opinions as well), many activities can benefit grooming unwillingly (more about that in the relevant chapter) and finally there are many things commonly found together with traditional child pornography (Gillespie, 2016, pp. 247-248). The US Supreme Court in the *Ashcroft v. Free Speech Coalition* concluded that prohibiting depictions of child pornography violated the First Amendment of the Constitution. The European Court of Human Rights in the case of *Karttunen v. Finland* in 2011 came to a different conclusion, stating that artists exercising freedom of expression are also subject to duties and responsibilities.

None of the international instruments contains a clear consensus in addressing the dilemma. The OPSC only refers to “child” and nothing indicates that this means anything other than a real child. The Budapest Convention’s scope also extends to “a person appearing to be a minor engaged in sexually explicit conduct” and “realistic images representing a minor engaged in sexually explicit conduct” (Art 9. Para. 2). The Lanzarote Convention contains the definition of “any material that visually depicts a child engaged in real or simulated sexually explicit conduct or any depiction of a child’s sexual organs for primarily sexual purposes” (Art. 20. Para 2). This means that the two CoE instruments both persecute virtual child pornography but there is an ‘opt-out’ option for all signatory states. The EU Directive 2011/93 clearly covers all type of material and is legally binding for all EU member states.

Self-Generated Content, Sexting, and Sextortion

Another important problem that must be addressed is the question of self-generated content or self-exploitation. This phenomenon stems from increased access and exposure to pornography and the increased sexualization of children in the media (Leary, 2008, p. 18). It means that minors create images depicting themselves naked or during sexual acts and then send these to others. With the rise of the use of mod-

ern ICTs among minors (including computers with built-in web cameras and smartphones with quality cameras), it is becoming more common that they create and forward these materials among themselves.

This activity is often called “sexting” (Merriam-Webster, 2012) and there are even applications which encourage this behavior, like Snapchat. Adults can also engage in sexting between each other so in itself it is not a behavior that can be prohibited. According to research conducted in 2011, 1/3 of European children between the ages of 14-18 have had contact with sexting (Atabekova & Filippov, 2018, p. 765). 70% of 18-19 year-olds surveyed in one study felt pressure from another party to participate in sexting (Váradi-Csema, 2016, p. 642).

It can be as harmful as any other form of sexual exploitation for children. For example, in Denmark, there was a case where a sex video depicting a couple of 15-year-olds was shared by numerous people (mostly students) on the internet, a thousand of whom now face charges (Sorensen, 2018). Europol warns that such material, even if initially shared with innocent intent, often finds its way to “collectors”, who often proceed to exploit the victim, in particular by means of extortion (Europol, 2018).

The law does not specify that child pornography must be created by others to be punishable which means that self-generated content is no exception from the law. Online predators can use it to blackmail children after they send them their first pictures and the scared minor is likely to continue sending more. This behavior is often called “sextortion”. Addressing the problem, the CoE’s Lanzarote Committee released their opinion in July 2019 (Lanzarote Committee, 2019). In their opinion, sexting by children should not be considered child pornography, when it is intended solely for their private use. And children coerced into such conduct should be addressed to victim support and not subjected to criminal prosecution.

Grooming

Grooming can be described as an act befriending minors and then inviting, inducing or coercing them into participating in or observing sexual acts and producing child pornography. Cyberspace facilitates this process in a way that communications can become intimate at a rapid speed (Clough, 2010, p. 332). Research shows that grooming is becoming less frequent as it requires a lot of time and effort to gain the trust of the victim. Now the period between initial engagement with a child and an offending outcome often can be extremely short (Greijer & Doek, 2016, p. 51).

According to a 2014 EU Survey, 20% of 14-16 years old children received sexual images online; 43% had contact online with someone they have not met face to face before, 11% sent their photo or video to these persons, and 14% met online contact offline (Atabekova & Filippov, 2018, p. 765). The Lanzarote Committee adopted an Opinion on the solicitation of children for sexual purposes through information and communication technologies (grooming) in 2015 (Lanzarote Committee, 2015). In this, it is stated that “the solicitation of children through information and communication technologies does not necessarily result in a meeting in person” (Art. 17). This means that grooming that only takes place in online space and does not include offline meetings can be as harmful as any other forms of grooming. Sexual offenses can be perpetrated online which leads to the production of child pornography.

Images of children engaged in sexual activity can be used as tools of grooming children for child pornography and sexual activity (Akdeniz, 2008, 22) and generated material, like the previously mentioned Deepfake videos can be used to encourage children to engage in sexual activity (Harris, 2019, p. 106). Seeing these, children might feel ‘left out’ and may be persuaded to participate actively in sexual activities (Váradi-Csema, 2016, p. 642).

According to O'Brien, there is a cycle of child pornography which first involves showing sexual material to a minor who is then convinced to participate in sexual acts which are filmed at a later stage, creating new material to attract other victims (Akdeniz, 2008, p. 5).

New Means of Distribution

The Budapest Convention requires parties to criminalize the distribution or transmission of child pornography through a computer system (Art. 9. (1)(c)). Although physical distribution was criminalized before the Convention, the increasing use of ICTs required this specification (Clough, 2010, p. 292). It is hard to decide what 'distribution' exactly means as it is undefined in international instruments or national legislations.

In 2006, it was estimated that there were more than 100,000 websites offering child pornography (Clough, 2010, p. 250). However, most of them are not on the surface web, which is well monitored. Dark Web plays a big role in distribution, which is accessible only through specialized applications, such as TOR (The Onion Router), where many criminal groups have been organized around the exchange and trade of child pornography content. Europol confirmed this in 2014, stating that the Darknets and other environments offering a high degree of anonymity are increasingly popular, especially among those with greater security awareness and IT knowledge. Such platforms host hidden services and marketplaces and are increasingly used by child sex offenders and producers (Jeney, 2015, p. 40). For example, the Lolita City community, the 1,500 members of which were eventually exposed by members of the Anonymous hacker group. The US-based pedophile group Candyman had about seven thousand members (Dornfeld & Mezei, 2017, p. 34).

The use of new technologies for distributing child pornography is becoming more regular. Two examples are peer-to-peer (P2P) or file-sharing networks and online streaming services. According to Europol, p2p networks are the main platform to access child abuse material and the principal means for non-commercial distribution. Meanwhile, online streaming means the profit-driven abuse of children overseas, the victims of which live in front of a camera at the request of Westerners (Europol, 2018).

The biggest problem in tackling streaming of material is that it is not covered in most of the international instruments as it is neither "acquisition" or "possession" of the illicit material. The Lanzarote Convention however criminalizes causing or coercing children to participate in child pornographic performances (Art. 21 (a)-(b)). However, it is only on the side of the perpetrator and as they are mostly located outside of Europe, often in Asia and Africa, therefore it is hard to prosecute them for these acts. Art. 24 criminalizes aiding or abetting such actions but it is questionable if simply watching a stream can be taken as such.

Anonymization and Encryption

The notion of anonymity is a very important factor for perpetrators when choosing to utilize the internet and ICTs. Two methods can achieve greater security for them in this regard: anonymization and encryption. While the first one aims at making communication more secure, the latter makes data accessible only to those who have the right encryption key to view it.

Anonymization devices include proxy servers and virtual private networks (VPNs), which allow users to easily obtain an IP address in any other country in the world. Another such tool is the TOR, developed by the United States for military purposes, which protects the content of communications using a hard-to-crack encryption method.

Until a few years ago, the use of steganography (hiding material in another, seemingly harmless file) was significant, but nowadays it is easy to filter out such files. Therefore, encryption programs, the effectiveness of which varies, are more commonly used now (Dornfeld & Mezei, 2016, 35). The nature of encrypted data remains unknown to the investigating authority and cannot be used as evidence. The question, therefore, arises as to whether the defendant may be required to provide the decryption key. In some member states, such as France, there is a provision in the Criminal Code (Art. 434-15-2), stating that the refusal to hand over the password or encryption key to the authorities is a criminal offense, while in Germany, for example, they intend to prevent this by using special police units and raids. In the United States, by contrast, such an obligation was found to be contrary to the prohibition of self-incrimination because the defendant effectively admits having unlawful information in the system.

Although detection is significantly more difficult if the offenders use for example proxy servers, passwords, encryption and/or steganography, according to a US study there are relatively few of them (20%) taking such steps. In addition, it must be noted that the survey was limited to those arrested so it might indicate that more people are actually applying the technology so successfully that they are virtually invisible to law enforcement (Clough, 2010, p. 250).

THE RESPONSE OF THE EUROPEAN UNION AND RECOMMENDATIONS

The European Union is involved in tackling online child pornography and other forms of sexual exploitation of children on many levels: policy, legal framework and institutional. The main legal instrument adopted was the Framework Decision 2004/68/JHA on combating the sexual exploitation of children and child pornography. Art. 3 of the Framework Decision requires the Member States to punish production, distribution, dissemination, transmission, acquisition or possession of child pornography and supplying or making available such material. Art. 8 (3) stated that if a Member State decides not to extradite its own citizen, it has to prosecute when the crime is committed by one of its own nationals outside its territory. Art. 8 (4) instructs Member States to ensure their jurisdiction in cases where the crime was committed by means of a computer system accessed from its territory, whether or not the computer system is in its territory.

In 2007, the European Commission reported that almost all of the Member States had ensured a high level of protection of children from sexual exploitation and abuse but there were problems not addressed by the existing legal regime (Jeney, 2015, p. 13). The Framework Decision proved to be inadequate for requiring proof of “explicit sexual conduct” but not abuse (Astinova, 2013, p. 27). In addition, in the three-pillar system of the EU, the Framework Decision was a rather weak form of secondary legislation, which suffered from many problems. It was similar in nature to Directives but unlike them, it had no direct effect and the transposition was not supervised, causing fragmentation (Dornfeld, 2016, p. 91). The EU’s previous legal regime regarding cybercrime (including online child pornography) was replaced both on a policy and on legislation level following the Treaty of Lisbon’s entry to force in 2009 (Buono, 2012, p. 332).

The first change was on a policy level. In 2009 in Prague at the Conference on ‘Safer Internet for Children - fighting together against illegal content and conduct on-line’ the ‘Prague Declaration’ was adopted. The Declaration is dedicated to the process of improving cooperation between all stakeholders in the field of promoting safer internet and mobile communications, especially for children (Buono, 2012, p. 337). There was a short-lived draft for a new Framework Decision on child pornography in 2009 (Herczeg, 2014, p. 71) but it was soon replaced by a new proposal for a Directive in 2010. This

was adopted in 2011 as the Directive 2011/93, the content of which was addressed before in this chapter on multiple occasions.

The first articles of the Directive are about the definitions, the offenses, aggravating circumstances, etc. There were provisions regarding ICT-based child pornography, like criminalizing pornographic performance (Art. 4(3)), which means forcing a child to participate in pornographic performances (like the streaming mentioned before). Causing and recruiting a child for such performances and attending them was also criminalized. Solicitation for sexual purposes (grooming) is also a new offense in the Directive (Art. 6). Arts 12-13 contain provisions on the liability of legal persons and the relevant sanctions, which are standard regulations in all criminal Directives but here they seem out of place. Although legal persons can also benefit from child pornography (for example trading these materials), there is no precedence of companies engaging in such behavior.

The most interesting provision of the Directive is Art. 25 is titled ‘Measures against websites containing or disseminating child pornography’. It also creates the opportunity for the Member States to create the legal basis for the prompt removal of web pages containing or disseminating child pornography hosted in their territory. If that is not possible, they can order internet service providers to block access to web pages containing or disseminating child pornography for Internet users within their territory. This is often called ‘internet blocking’ and is associated with authoritarian regimes like Russia, Turkey or China. The most serious problem with this solution is that, as it was presented in the chapter, the distribution of child pornography no longer takes place on the surface web. As other areas (like the deep web) is already hidden from the average user, the provision for internet blocking is redundant.

In the proposal of the Directive, the European Commission originally intended to impose a mandatory blocking obligation on the Member States if the effort to remove was unsuccessful. However, during the legislation process, concerns were raised like the potential breach of the right to freedom of expression, lack of adequate legal remedies against blocking measures, the inefficiency of blocking techniques considered easy to circumvent, potential censorship, “overblocking” (i.e. blocking of legal content), etc. So a compromise was reached, making this an optional measure for Member States (Jánoskúti, 2016, p. 74). The biggest fear was that if the states were bound to block the sites containing child pornography it would mean that computer systems and access to websites were to be monitored and confiscation of internet data without authorization could occur (Astinova, 2013, p. 32). In 2016, in total 13 Member States adopted regulation for blocking Internet sites. These are Belgium, Cyprus, France, Greece, Hungary, Italy, Lithuania, Luxembourg, Poland, Portugal, Romania, Spain and Sweden (Jánoskúti, 2016, p. 79). In Hungary, the system is not functioning well, as there were zero sites blocked for child pornography in 2016. Blocking is instead used as a tool to combat illegal online gambling and the selling of fake medicine (Dornfeld & Mezei, 2016, p. 35).

Useful tools for enforcing the provisions of the Directive are the EU’s mutual recognition instruments, which abolish the double criminality requirement with respect to child pornography. Among others, this includes the European Arrest Warrant, the European Investigation Order and the Directive on Confiscation (Jeney, 2015, p. 20). However, these are mostly useful for gathering offline, physical evidence and not e-evidence. Addressing this problem, in 2019 the EU introduced its e-evidence proposal: A Directive and a Regulation. It introduces the “European Preservation Order” and the “European Production Order”. The first one is about preserving data for later confiscation while the latter allows law enforcement to directly request electronic data from any service provider offering services in the EU, irrespective of where the provider’s headquarters are located or where the respective data is stored physically. This is a very big step forward for European legislation.

On a policy level, the EU has adopted the Digital Agenda for Europe as one of the pillars of the Europe 2020 Strategy. As a part of achieving these goals, the European Commission drafted a ‘Strategy for a Better Internet for Children’, which proposed a series of actions to be undertaken by the European Commission, EU Member States and by the ICT industry (Jeney, 2015, p. 23). Victim identification is an important step in tracking down online child pornography, preventing victimization and stopping the further spread of damaging material. Interpol, for example, created an international image database on child sexual exploitation in 2009, providing real-time access to the collected footage, and its February 2016 version provides the ability to analyze video footage (Dornfeld & Mezei, 2017, p. 34). This approach should be strengthened in the EU as well. There is no obligation for the Member States to introduce the registration of sex offenders, as they have the option not to create such a register and there is no European level equivalent either. This means that offenders can easily avoid professional disqualification by cross-border movement, which is unimpaired in the European Union (Jeney, 2015, pp. 42-43).

There were changes in the institutional framework as well. The biggest of those is the establishment of the European Cybercrime Centre (EC3) as a part of Europol. As the Europol has no legal basis to conduct investigations directly, its main goal is to coordinate the work of the Member States’ law enforcement agencies. EC3, in particular, focuses on the fight against online crime that causes serious harm to the victim, including sexual exploitation of children and child pornography. According to a report on the first year of organization, the center was involved in nine large-scale operations against child sexual abuse in 2013 (Dornfeld & Mezei, 2016, 36). Working alongside EC3 is the Joint Cybercrime Action Taskforce (J-CAT), which works on the most important international cybercrime cases, including online sexual exploitation of children that affect the EU Member States and their citizens.

FUTURE RESEARCH DIRECTIONS

There are many topics not addressed in detail in this chapter that are open to future research. One of those is the question of jurisdiction, as the problem of child pornography is a global one, while the legislation response is mainly on a national level. The topic of criminal cooperation is also an interesting one, as there are many cross-border cases and the tools at the disposal of law enforcement are mostly outdated. Legal and investigational responses to the threat of anonymization and encryption is also a hotly debated and interesting topic to research. Victimology and the criminological aspects of increasing youth indecent communication can be potential future areas of research as well.

CONCLUSION

As the chapter shows, online child pornography is a highly complex social phenomenon that targets the most vulnerable in society and recently became an even larger threat due to the rapid development of ICTs. From the start, there are many controversial topics, including the proper term for the phenomenon. One cannot find a settled agreement on the definition, which is not an entirely academic question, as it raises practical issues as well. For example, double criminality is required for law enforcement to request mutual legal assistance from other agencies abroad. There is no unified approach to define child pornography and more harmonization is required on both international and regional level.

The methods of committing the crime are rapidly evolving due to new ICTs. It is hard for legislation and law enforcement to keep up with these new developments. Streaming is currently only punishable

on the creator's side, not the consumer's. File-sharing, deep web groups and other places provide the suitable environment for perpetrators to engage in trading and exchanging these materials. They cover up their tracks and hide evidence using other technologies, such as anonymization and encryption. However, the problem is not entirely technological but also social in nature. Minors use technology to shape their personalities and often engage in indecent communication like sexting, which can be used by predators to coerce them into participating in future child pornographic materials (grooming, sexting). A "cycle" of child pornography can be found.

EU's current legislation, policy and institutional framework is quite effective. However, there are some problems as well, like the utilization of the ineffective tool of internet blocking, the lack of EU-level registration of sex offenders and the lack of engagement in identifying victims. These questions have to be addressed in the future to provide an even better protection on a regional level. The other big problem, however, is much harder to deal with. As online child pornography is a global phenomenon, perpetrators can easily hide outside the EU, like in East and South Asia. A global approach and cooperation is a very important issue for the future.

KEY TERMS AND DEFINITIONS

3

Anonymization: A process of destroying online tracks of the data that could be used to link it to its originator.

Encryption: The process of encoding a message or information in such a way that only authorized parties can access it.

Grooming: The solicitation of children for sexual purposes.

Internet Blocking: Blocking access for users to certain Internet sites on a national level.

Sexting: A common practice among young persons, which involves taking sexually explicit images of one's self and sending it to others via ICTs.

Sextortion: A form of sexual exploitation during which the victim is coerced to provide sexual favors (including child pornography material) to the perpetrator.

Virtual Child Pornography: Child pornography produced by digitally modifying pre-existing images or fully generated by a computer.

Regulating Misandry: Expanding the Protection Against Online Hate Speech

INTRODUCTION

Internet and social media have become a significant weapon to disseminate and share information around the globe. Yet, the above mentioned are also being misused for hate-crime activities. Hate crimes are criminal offences motivated by prejudice and committed against someone's identity, such as race, national origin, religion and/or other characteristics.

Perpetrators of such crimes are now able to reach a wide audience easily and inexpensively and they are able to carry out such activities in the digital world and commit criminal offences on the basis of prejudice and of certain immutable and innate characteristics of the victim. The so-called hate crimes target groups, such as women and children, disabled people and refugees.

Another type of hate crime can also be consider the online hate speech, or "cyberhate", under specific circumstances. A quite recent research revealed that men - along with women - can also be considered as victims of online hate crimes/cyberhate. More specifically, an Australian survey revealed that 54% of the victims of the reported incident of online abuse were men. The survey also pointed out that men were often subjected to abuse and insults, trolling and malicious gossip and/or rumours.

In the United Kingdom at the same time, the British Law Commission has already decided to review the existing legislation on hate crime. As the 40% of the victims of abuse are men, the Law Commission deliberated to extend the groups of people which could be considered as hate crime victims and be protected by hate crime legislation by including women, men and elderly people.

To that extent, the present contribution focuses on the inefficiencies of the existing legislative measures regarding the online hate speech and demonstrates some good practices. It also gives a general overview of the notion of "misandry" and how it is expressed in the digital world. Finally, it emphasises the need for particular protective measures, not only for women and children, but also for men.

BACKGROUND

Internet has the ability to cross borders, to repeal the existing distances and to set aside the communication barriers (Johnson & Post, 1996, pp. 1347 – 1402). Moreover, internet and social media have become a significant weapon to disseminate and share information around the globe. Still, these digital tools are also being misused for hate-crime activities.

Hate crimes are defined as criminal offences motivated by prejudice and committed against someone's identity, such as race, national origin, religion and/or other characteristics. The perpetrator of a

DOI: 10.4018/978-1-5225-9715-5.ch039

hate crime selects the victim based on its membership of a particular group. In some cases that the crime involves damage to property, and in these cases the property is chosen as well because of its association with a victim group. Furthermore, prejudice or bias could be defined as a preconceived negative opinion, intolerance or hatred directed at a particular group. The group must share a common characteristic that is immutable or fundamental, such as “race”, ethnicity, language, religion, nationality, sexual orientation, or other characteristics (Organisation for Security and Cooperation in Europe, 2014, pp. 21 - 22).

Since internet became very popular, “cyberhate” has emerged as a type of hate speech (Williams, 2006). “Cyberhate” has been manifested as the hateful speech used in an online communication. In particular, cyberhate is connected with social media platforms, such as Facebook and Twitter (Gerstenfeld, 2013; Awan & Zempi, 2016). Unfortunately, there is not a globally accepted current definition of what “cyberhate” consists. For instance, the United States Anti-Defamation League defined cyberhate as “any use of electronic communications technology to spread anti-Semitic, racist, bigoted, extremist or terrorist messages or information. To these, electronic communications technologies belongs the Internet as well as other computer and cell phone-based information technologies” (Anti-Defamation League, 2010). Yet, most of the cyber hate definitions are based on the definition of hate speech or rather hate crime itself.

“Cyberhate crimes” and hate crimes in general target groups, such as women and children, disabled people and refugees. However, a recent study showed that men can also be considered as victims of online hate crimes/cyberhate. The Australian survey demonstrated that 54% of the victims of online abuse were men (Hunt, 2016). The survey also pointed out that men were often subjected to abuse and insults, trolling and malicious gossip and/or rumours.

At the same time, the United Kingdom Law Commission has already decided to review the possibility of extending the already existing legislative protection against hate crime so as to make the current legislation more effective. In fact, the UK Law Commission is examining whether it is necessary to add more features in the protective sphere, such as gender characteristics, age and belonging to a specific subculture (United Kingdom Law Commission, 2018). Since 40% of the victims of abuse are men, the Law Commission deliberated to extend the groups of people which could be considered as hate crimes victims and covered by hate crime legislation by including women, men and elderly people (United Kingdom House of Commons, 2018, p. 9).

The above leads to the following aspects to be examined: First of all, there will be a review of the current international and national legislative framework on regular hate crimes and hate crimes committed in the digital world. Following the review of the existing legislative framework, the present contribution seeks to raise the inefficiencies of the existing legislative measures with regards to the online hate speech and to recognise some good practices. It also reviews the notion of “misandry” and how it is expressed throughout the digital world. Finally, it emphasises the need for particular protective measures, not only for women and children, but also for men.

International and Regional Legal Texts on Hate Crime

Hate crime is grounded in the principles of equal rights and tolerance which are incorporated in several international and regional human rights legal texts. To this end, the national policies and legislative measures towards the prevention of hate speech are developed to fulfil the international standards and to comply with the obligations of States. Therefore, to identify the effectiveness of the online hate speech regulations, it is worth pointing out briefly some of the most important international and regional legal instruments applicable to this matter.

International Legal Materials

International Covenant on Civil and Political Rights (ICCPR)

International Covenant on Civil and Political Rights (ICCPR) of 1966 constitutes the most important – after the Universal Declaration of Human Rights – legal instruments in the field of the protection of human rights. Article 20, para. 2 introduces that “[...] any advocacy of national, racial or religious hatred that constitutes incitement to discrimination, hostility or violence shall be prohibited by law [...]”. This article should be read with the limitation of the freedom of expression set out in article 19, para. 3, of ICCPR. It highlights that some limitations are “[...] necessary: (a) for respect of the rights or reputations of others; (b) for the protection of national security or of public order or of public health or morals [...]”.

The Human Rights Committee has explained further the difference between the two norms. In General Comment No. 34, the Human Rights Committee argued that “[...] what distinguishes the acts addressed in article 20 from other acts that may also be subject to limitations, is that for the acts addressed in article 20, the Covenant indicates the specific response required from the State: their prohibition by law. It is only to this extent that article 20 may be considered as *lex specialis* with regard to article 19. The acts referred to in article 20, paragraph 2, must cumulatively (a) advocate, (b) be for purposes of national, racial or religious hatred, and, (c) constitute incitement to discrimination, hostility or violence. By “advocacy” is meant public forms of expression that are intended to elicit action or response. By “hatred” is meant intense emotions of opprobrium, enmity and detestation towards a target group “Incitement” refers to the need for the advocacy to be likely to trigger imminent acts of discrimination, hostility or violence. It would be sufficient that the incitement relate to any one of the three outcomes: discrimination, hostility or violence [...]” (United Nations Human Rights Committee, 2011).

The exercise of violence is the main result of the commission of a hate speech crime. This violence aims to diminish the rights and the freedoms of the targeted group by making it an object of discrimination. Moreover, hate speech is also used to stereotype a group by identifying and highlighting one or more of its negative characteristics.

United Nations Convention for the Elimination of Racial Discrimination (CERD)

Apart from ICCPR, the Convention for the Elimination of Racial Discrimination (CERD) also emphasises the obligation of States to respond to extreme manifestations of hate speech. Article 4 of the CERD encourages State Parties to “[...] condemn all propaganda and all organizations which are based on ideas or theories of superiority of one race or group of persons of one colour or ethnic origin, or which attempt to justify or promote racial hatred and discrimination in any form, and undertake to adopt immediate and positive measures designed to eradicate all incitement to, or acts of, such discrimination and, to this end, with due regard to the principles embodied in the Universal Declaration of Human Rights and the rights expressly set forth in article 5 of this Convention, *inter alia*:

- (a) Shall declare an offence punishable by law all dissemination of ideas based on racial superiority or hatred, incitement to racial discrimination, as well as all acts of violence or incitement to such acts against any race or group of persons of another colour or ethnic origin, and also the provision of any assistance to racist activities, including the financing thereof;

- (b) Shall declare illegal and prohibit organizations, and also organized and all other propaganda activities, which promote and incite racial discrimination, and shall recognize participation in such organizations or activities as an offence punishable by law;
- (c) Shall not permit public authorities or public institutions, national or local, to promote or incite racial discrimination [...].

Additionally, General Recommendations No. 7 and No. 15 of Committee of CERD reaffirmed the requisite character of this obligation (United Nations Committee on the Elimination of Racial Discrimination, 1985). For instance, General Recommendation n. 15 explains further that States have to monitor that the appropriate legislation is enforced (United Nations Committee on the Elimination of Racial Discrimination, 1993).

Regional Legal Texts

European Convention on Human Rights (ECHR)

Similar provisions can be found in regional human rights instruments. Article 10 of the European Convention on Human Rights (ECHR)¹ states that “ [...] everyone has the right to freedom of expression. This right shall include freedom to hold opinions and to receive and impart information and ideas without interference by public authority and regardless of frontiers [...]”. Similarly, the European Court of Human Rights (ECtHR) emphasised that the freedom of expression constitutes a fundamental value of democracy and the rule of law. More precisely, the ECtHR advised that the freedom of expression is not only applicable to “ [...] information or ideas that are favourably received or regarded as inoffensive or as a matter of indifference, but also to those that offend, shock or disturb [...]” (European Court of Human Rights, *Handyside v. United Kingdom*, 1976).

Council of Europe Additional Protocol to the Convention on Cybercrime 2003

The Additional Protocol to the Convention on Cybercrime was adopted in 2003 in order to criminalise acts of racist and xenophobic nature committed through computer systems. At the time of its adoption, there was an important need for suppression of racist and xenophobic acts and on the other hand a need for balance the freedom of expression through computer systems. More particularly, it is highlighted that the signatory parties of the Protocol should “(...) adopt such legislative and other measures as may be necessary to establish as criminal offences (...) distributing, or otherwise making available, racist and xenophobic material to the public through a computer system”.

European Union Council Framework Decision 2008/913/JHA on Racism and Xenophobia

The Council Framework Decision 2008/913/JHA of 28 November 2008 on combating certain forms and expressions of racism and xenophobia by means of criminal law recognises that hatred and violence against persons or a group of persons based on their race, colour, religion, descent or national or ethnic origin constitutes a serious threat and should be criminalised. More specifically, according to the Framework Decision, the public incitement to the abovementioned acts and/or their commission by public dissemination or distribution of pictures and other material have to be punishable².

American Convention on Human Rights (ACHR)

Article 13 of the American Convention on Human Rights (ACHR)³ sets out that “ [...] everyone has the right to freedom of thought and expression. This right includes freedom to seek, receive, and impart information and ideas of all kinds, regardless of frontiers, either orally, in writing, in print, in the form of art, or through any other medium of one’s choice [...]”. The above mentioned article includes a more narrow approach of the Article 20 of ICCPR. The text of art. 13 (5) is the following, “Any propaganda for war and any advocacy of national, racial, or religious hatred that constitute incitements to lawless violence or to any other similar action against any person or group of persons on any grounds including those of race, colour, religion, language, or national origin shall be considered offenses punishable by law”. In fact, it fails to include “hostility” and “discrimination” among the aims pursued by hate speech and resorts rather vaguely to the expression “any other similar action” (American Convention on Human Rights, Article 13).

African Charter on Human and Peoples’ Rights (ACHPR)

The African Charter on Human and Peoples’ Rights (ACHPR)⁴ highlights that “ [...] 1. every individual shall have the right to receive information. 2. Every individual shall have the right to express and disseminate his opinions within the law [...]” (African Charter on Human and Peoples’ Rights, Article 9).

In other words, all of the international and regional legal instruments prescribe limitations on freedom of speech in cases that the speech is discriminatorily aimed at individuals (Webb, 2011, pp. 446 - 447).

Effectiveness of the Current Regulations on Online Hate Speech

Despite the existing regulations with regards to the protection of individuals by online hate crime violations, there are several recorded violations as shown on the existing national case law. The case law revealed how difficult is for States to comply with the online hate crime regulations. It also acknowledges the different approaches adopted by European States and the United States of America. This resulted in problems within the realm of the jurisdictional and technical implementation of regulatory orders (Alkiviadou, 2017). The main reason for this is the fact that the online world has no frontiers and it is very easy for multiple jurisdictions to be involved in an online hate crime case.

The Fredrick Töben case

In 1999, Fredrick Töben was arrested - while he was visiting Germany - because he had uploaded anti-Semitic material and information onto his website, an action that was violating Germany’s Holocaust Law. The website was registered in Australia. Thus, a court of first instance argued that Germany is not able to control that material of his website. However, the German High Court reversed this decision and pointed out that “German authorities may take legal action against foreigners who upload content that is illegal in Germany – even though the Websites may be located elsewhere” (Van Blarcum, 2005). This example case revealed the broad interpretation given by the German courts to the exercise of jurisdiction for matters with regards to internet.

THE YAHOO! INC. V. LA LIGUE CONTRE LE RACISME ET L'ANTISÉMITISME CASE

The case of *Yahoo! Inc. v. La Ligue Contre Le Racisme et L'Antisémitisme et al* was another case that demonstrated the legal and technical consequences of jurisdictional issues regarding internet regulations (*The Yahoo! Inc. v. La Ligue Contre le Racisme et L'Antisémitisme*, 2001). In 2001, the League against Racism and Anti-Semitism and the Union of Jewish Students of France issued proceedings against Yahoo! for offering souvenirs of Nazi for auction on its website. Yahoo! recalled the boundaries of the French law jurisdiction as the content was uploaded in the United States of America where the conduct and material was permitted under the First Amendment. Yet, Yahoo!'s argument was not accepted by the court. The French court “applied an effects-based jurisdictional analysis and granted prescriptive jurisdiction describing the sale of Nazi paraphernalia” (Bank, 2010, p. 235). Therefore, the French Court held that Yahoo! was liable for its effects in France under the R. 645-1 of the French Criminal Code (R. 645-1 of the French Criminal Code outlaws the sale, exchange or display of Nazi related materials or Third Reich souvenirs). Moreover, the French court requested from Yahoo! to confirm that French citizens would not have access to the auctions of Nazi objects; Yahoo! was also subjected to 100,000.00 francs for every failure to comply with the order (*The Yahoo! Inc. v. La Ligue Contre le Racisme et L'Antisémitisme*, 2001). The order further summarised that Yahoo! should “take all necessary measures to dissuade and render impossible any access via Yahoo.com to the Nazi artifact auction service and to any other site or service that may be construed as constituting an apology for Nazism or a contesting of Nazi crimes” (*The Yahoo! Inc. v. La Ligue Contre le Racisme et L'Antisémitisme*, 2001).

Besides, the French Court commented upon the jurisdictional application of the order by underlining that the main issue in this case was whether it was “consistent with the Constitution and laws of the United States for another nation to regulate speech by a United States resident within the United States on the basis that such speech can be accessed by Internet users in that nation” (*The Yahoo! Inc. v. La Ligue Contre le Racisme et L'Antisémitisme*, 2001).

The Yahoo! case confirmed again the wide range of technical issues and legal consequences of jurisdictional application with regards to internet regulations. Taking into account the absence of actual and physical borderline of the internet and the use of social media, it is easy not easy enough to control and monitor someone's access to information. For instance, someone has access to a kind of material which is a criminal offence for his country. Like France and United States of America in this case, States meet legal obstacles in case that they decide to set restrictive measures for the material available online. In fact, the notion of the territorial use of internet has a different meaning in the digital and social media era (Bank, 2010, p. 235).

The Warman v Kyburz case

In 2002, the *Warman v Kyburz* case dealt with anti-Semitic content of Kyburz' website. More specifically, a lawyer named Richard Warman turned against Fred Kyburz who was accused of disseminating hateful content for Jewish people, by violating the Canadian Human Rights Act. The Canadian Human Rights Tribunal examined the problems raised with regards to the internet borders (*Warman v Kyburz*, 2003). In particular, the Canadian Human Rights Tribunal argued that, due to the nature of internet “including the jurisdictional challenges arising from the borderless world of cyberspace, as well as the ‘moving targets’ created by the use of mirror sites, raise real concerns as to the efficacy of cease and desist orders in relation to hate messages disseminated on the Internet” (*Warman v Kyburz*, 2003).

FOCUS OF THE ARTICLE

Current Challenges of the Regulation on Online Hate Crime

The above cases reflected some of the major difficulties related to the regulation of the online hate crime activities based on jurisdiction. Yet, the notion of jurisdiction of the internet remains unclear due to its borderless nature (Alkiviadou, 2017). Regional judicial human rights mechanisms, such as the European Court of Human Rights and national courts have interpreted the notion of jurisdiction more broadly. However, the contribution of the judiciary bodies - regional and national - does not stay only on the examination of the jurisdiction and/or anti-Semitic cases.

Nowadays, online hate crime activities have the form of hurtful comments across all social media platforms (trolling), online threats against a person, group of people or organisation, disclosure of private sexual images without consent, online harassment (sexual or psychological), grooming, online stalking and virtual mobbing. Individuals who are considered as victims of those crimes are often people who belong in vulnerable groups, such as women, children, people with disabilities (Fundamental Rights Agency, 2015), LGBTQI, immigrants and refugees. The so-called “cyberhate” does not have a standard definition, but all the aforementioned activities (or lack of actions) are included, as forms of it (Asko, 2017).

The UK Home Affairs Committee referenced that women are the main victims of harassment on social media. The most common type of harassment is sending sexist messages. Women who are using twitter have witnessed that they have received abusive messages. At the same time, around a third of women experienced “politically extremist hate messages, unwanted sexual messages or images, stalking, and threats of violence” (United Kingdom House of Commons, 2018, p. 8). This is the main reason that the UK Law Commission started negotiations in order to include misogyny as a separate hate crime (United Kingdom House of Commons, 2018b).

Moreover, online harassment and cyber hate crime can also affect children. Cyber bullying is defined as bullying (abusive behaviour) that is taking place through digital means, such as electronic devices. Trolling messages and threats, sending, posting, or sharing negative or harmful content about someone else at online fora constitute a form of cyber bullying. Since 2015, in the United Kingdom, 4,541 child line counselling sessions were taken place whereas cyber bullying was mentioned. This was a 13% increase within 2 years' time (United Kingdom House of Commons, 2017).

In the digital era and hidden behind a computer screen, both men and women could be equally considered as victims. A recent Australian research reveals that men are victims of online harassment. A 54% of the victims of online abuse were men (Hunt, 2018). The survey also pointed out that men were often subjected to abuse and insults, trolling and malicious gossip and/or rumours (Hunt, 2018). Simultaneously, in the United States of America almost 20% of the complaints with regards to sexual harassment complaints at work were filed by men. Similarly, a UK survey found that 20% of men had experienced of sexual harassment in the United Kingdom. The same survey also revealed that 79% of male victims kept it to themselves because of the fear of embarrassment in case of raising a complaint and the concern that their complaints will not be taken seriously (Lapin, 2018). In other words, along with misogyny, misandry would constitute a major concern for the modern societies in the online hate crime regulation.

Misandry [deriving from the Greek words *μίσος* (hatred) and *άνήρ* (man)] is defined as “the hatred of men”, “the feeling of hating or strongly disliking men, or being prejudiced against them”. Dr. Paul Nathanson and Dr. Katherine Young note that the term “misandry”, “like misogyny, (...) is culturally propagated hatred”. The UK Law Commission is currently preparing a review project of hate crime legislation. More particularly, it intends to review the range of protected characteristics and the potential

need of including more characteristics under the legislative protection. The crimes motivated by hatred based on gender characteristics (misogyny and misandry) are going to be reviewed on whether they can be classified as hate crimes.

However, the national regulation on the online hate crime should not be ‘gender based’. All individuals should enjoy the same rights and should have equal protection by the law. In case that a State adopts a ‘gender based’ regulation on online hate crimes, it looks that it appoints one gender always as the perpetrator of the online hate crime and the other as the victim. But, if States deviate for the adoption of a ‘gender based’ approach towards their national policies, this will fail to address misogyny as the main issue. It will also lead to reporting misandry online hate crime incidents. Besides, seventy years after the adoption of the Universal Declaration of Human Rights, domestic regulations that provides with special protection to women seem to be anachronistic, whilst Article 20 of the EU Charter confirms that everyone is equal before the law.

The issue of online hate is moving in new dimensions. Perpetrators of online hate speech find an array of possibilities to use and abuse the internet for purposes of victimisation. On the other hand, victims - both women and men - have been exposed to dangers due to the misuse of the social media platforms. Quite recently, more than 1,300 cases of sextortion were reported to the UK National Crime Agency and the UK Anti-Kidnap and Extortion Unit (AKEU) by the police across the UK. According to this, organised groups are using fake profiles on social media and/or dating websites in order to befriend victims - mostly young males aged 17-25 - and encourage them to livestream sexual activities which are recorded and then they threaten them to share with the victim’s friends and family unless they are paid. At least five British men and boys have killed themselves after being targeted of sextortion (Dearden, 2018).

SOLUTION AND RECOMMENDATION

The above reveals that victims of the online hate crime are not only women.

The need to enact proper legislative measures to promote the safe use of internet and social media is more than necessary. Unfortunately, even if the internet’s capacity is to promote the communication around the globe, in some cases internet is used by some people - individual and/groups - to transmit anti-Muslim and anti-Semitism ideologies, racism and xenophobia feelings, homophobia, misogyny and misandry and other forms of hate. This type of hate can be found on several websites and blogs, as well as in chat rooms and social media.

States lately have adopted national action plans on how to respond to online hate crimes. In some countries as the United Kingdom, the online hate crime is treated the same as the face-to-face hate crime. However, the real challenge on this matter is how to tackle online hate crime efficiently and follow the rapid development of technology.

The emergence of the online world and social media platforms has increased the practice of self-regulation. Self-regulation is the technique of a social media platform to develop its own policy and use regulatory tools for its users; nowadays, it is considered as the most preferred approach for combating online hate speech, although it also needs improvement, as self-regulation itself does not guarantee effectiveness and efficient protection. In order for self-regulatory tools to be effective, it is important to present a strong

On 31 May 2016, the European Commission, together with Facebook, YouTube (Google), Twitter and Microsoft, agreed a ‘code of conduct’ on fighting hate speech. To this end, in 2018, German police officers have the responsibility to undertake a crackdown on racist or xenophobic social postings at a

national level, as a result, they traced the identity and the homes of 36 people suspected of being behind the posts. At the same time, Germany has approved a new bill regarding the punishment of the social networking sites in case that they fail to remove illegal content such as hate speech and/or defamatory fake news. If they fail to do so, the laws impose fines of up to 50 million euros on Facebook, Twitter and other social media platforms.

Online Hate Crimes Against Women (CYBER VAWG)

3

Tehmina Khan

RMIT University, Australia

INTRODUCTION

Misogyny takes numerous forms in the context of social systems and organisations. Manne (2018) describes it as a serious issue that results from discomfort and hostility when a well-entrenched system of social norms is challenged. Women who challenge gendered norms or expectations, who disrupt or pose a threat to gendered social hierarchies or powerful women who do not yield their power in service of men's interests face misogyny (ibid.) or cyber violence (cyber VAWG). The key objective in this article is to provide a detailed meaning and consideration of cyber VAWG with numerous real-life examples provided in literature and to analyse its potential impacts. A literature review of academic and non-academic articles has been undertaken to identify the meaning of cyber VAWG, its impacts and recommendations to tackle cyber VAWG.

BACKGROUND

The increasing availability of internet and access to social media by the masses has resulted in the increasing occurrences of cyber violence against women and girls (cyber VAWG). The term cyber VAWG encompasses multiple forms of exhibitions of violence against females in the online environment ranging from hostility to threats, exploitation and sexual harassment. Cyber VAWG is an additional layer of misogynistic practices, undertaken in the online environment. Manne (2018) has critically described misogyny as a branch of a patriarchal order with the objective of exercising control, power and subjugation, while maintaining the governing ideology of hostility against females. Gender imbalance, gender inequality and gender segregation in the real world, in organisations and professions impact the content which is produced, commercialised and disseminated; misogynistic behaviours are now rapidly increasing online (Swaminathan, 2014).

According to Ging and Siapara (2018) certain types of females have become key targets for online shaming, or “digital pillory.” Hess and Waller (2014) have identified these females as social justice warriors (SJW), the “slut” (as labelled by misogynists)- women in tech and gaming who have dared to challenge entrenched norms of the IT industry which is still male dominated, or any woman who is perceived as publicly questioning or disrupting gendered power relations. The “slut” is a derogatory term used for a woman who promotes any aspect of feminism or women's rights in the online medium.

The disciplining function of online discourses against these women as Alvares (2018) has identified, becomes a means of violent reinforcement of gendered power relations through online misogyny. Cole (2015) has captured the experiences of women who publicly promote women's rights or any aspect related to feminism through the following quotes: Christina (2012), a blogger “get[s] this all the time. I get this so often, I've lost track. As has every other woman I know who speaks publicly about feminism.”

DOI: 10.4018/978-1-5225-9715-5.ch040

Journalist and blogger Jessica Valenti (2014) has been quoted by Cole (2015) about projecting her views on Facebook: “I spen[t] the better part of the day fielding tweets and messages about what a slut I am. That I should be ‘jizzed on’ ... that I want to be gangbanged, that I’m worthless.” As identified by Cole (2015) and in various other published works on misogyny through social media, rape is the most frequently used threat in response to women online (Stanton, 2011). The threat of rape in a large portion of tweets is often accompanied by an emoticon or an acronym such as “LOL,” or a joke; humor is used in order to make the violence socially acceptable and remains as a part of the disciplining process (Cole, 2015). Doyle (2011) re-emphasizes the gendered nature of violent discourse committed online as “What matters is not which guys said it: What matters is that, when you put their statements side-by-side, they all sound like *the exact same guy*. And when you look at what they’re saying, how similar these slurs and insults and threats we get actually are, they always sound like they’re speaking to *the exact same woman*. When men are using the same insults and sentiments to shut down women ... we know that it’s not about us; it’s about gender”. Regardless of which legislation is looked at, threat to commit rape is considered a sexual offence. Rape threats are not the only forms of cyber VAWG undertaken in the online environment. There are numerous other types of cyber VAWG. The objective of this Chapter is to consider cyber VAWG in detail based on a review of prior academic and non-academic literature. Numerous real-life examples of cyber VAWG and cyber misogyny are provided to highlight types of cyber VAWG and the extremely negative impacts of VAWG crimes.

METHODOLOGY

Searches were undertaken in Google Scholar and Google using search terms such as Cyber violence against women and girls, ‘cyber bullying’, ‘cyber violence’, ‘cyber violence against women and girls’, ‘online harassment’, and iterations thereof between October and November 2018. Multiple government reports and media coverage as well as academic literature on the topic of cyber VAWG were identified. These have been cited. The approach adopted in this article has been a review of academic and non-academic literature on cyber VAWG.

Cyber Misogyny/VAWG Hate Crimes

Gender violence has been defined by the UN Committee on the Elimination of Discrimination against Women (CEDAW), general Recommendation 19 as “violence that is directed against a woman because she is a woman that affects women disproportionately. It includes acts that inflict physical, mental or sexual harm or suffering, threats of such acts, coercion and other deprivations of liberty (CEDAW, 1992). CEDAW’s general recommendation 35 extends gender-based violence against women to multiple forms including in technology mediated settings and redefines gender based violence through technology mediated environments occurring in internet and digital spaces as cyber VAWG (CEDAW, 2017).

There are numerous terms which are used to describe online hate crimes specifically targeted against women including: gendered cyber hate, technology-facilitated violence, tech-related violence, online abuse, hate speech online, digital violence, networked harassment, cyber bullying, cyber harassment, online violence against women (VaW), and online misogyny (Ging and Siapera, 2018). References to these multiple terms as used in literature are used to capture the forms of gendered online abuse, the impacts of the abuse, implications as well as recommendations to mitigate the issue. Technology related human rights violations are defined in UN General Assembly’s (2013) Consensus Resolution as “

information-technology-related violations, abuses and violence against women, including women human rights defenders, such as online harassment, cyber stalking, violation of privacy, censorship and hacking of e-mail accounts, mobile phones and other electronic devices, with a view to discrediting them and/or to incite other violations and abuses against them...” (UNGA, 2014).

For cyber VAWG to occur, the main condition which needs to be met is the availability of Internet. Fifty-six per cent of the world population has access to the Internet and in most countries male access to the Internet is more than female access except in the Americas where it is roughly equal. A social networking platform has been found to act as the most popular medium for cyber VAWG (Ottawa Coalition to End Violence Against Women, 2016). The internet and its various platforms are now acting as a medium to promote toxic masculinity and as a result cyber-misogyny.

Cyber misogyny hate crimes are prevalent and increasing in societies and cyber VAWG has been declared as being of pandemic proportion with limited accountabilities enforced against perpetrators (UN Broadband Commission for Digital Development Working Group on Broadband and Gender, 2015). Anonymity is a key feature of online engagement and according to Zimmerman (2016) deindividuation which encourages people to exhibit violent, disinhibited behaviour, loss of control and personal constraint turns into “cyber dis-inhibition that occurs mainly because of the anonymous nature of the internet. Individuals may behave in ways that contradict normative behaviour when they do not identify with a particular online community and are free to leave without desire to return (...) individuals are able to freely make any statements, act in any online behaviour available, or even be whoever they want to be, only to simply log off at the end of the day. This ability to disconnect might trump the need for permission to behave in certain ways”. There are additional factors which have resulted in increasing cyber VAWG:

Action-at-a-Distance: Abuse can be undertaken anytime, anywhere without physical contact (there is a much greater level of flexibility offered in the online environment),

Automation: The use of technology requires less time and environment comparatively speaking to the physical environment,

Accessibility: Due to greater accessibility by many to social media platforms for example, there is a much larger audience to witness the abuse; a source of perhaps greater satisfaction for the perpetrator,

Propagation and Perpetuity: Texts and images can potentially exist for a very long period of time (Fascendini and Fialová, 2011). This factor adds to the potential of leaving an impact, a mark for a long period of time.

According to recent research undertaken by Pew Research Center women are about twice as likely as men to say that they have been targeted as a result of their gender (11% vs. 5%) online (Duggan, 2017). The research also found that women, especially young women face sexualized forms of abuse at much higher rates than men. 21% of women aged 18 to 29 reported being sexually harassed online, a figure that is more than double the share among men in the same age group (9%). In addition, roughly half (53%) of young women ages 18 to 29 have stated that someone had sent them explicit images they did not ask for. As far as the impacts of sexual harassment online are concerned for 35% of women who had experienced any type of online harassment described their most recent incident as either extremely or very upsetting, about twice the share among men (16%). A similar finding has been confirmed by Amnesty International whose 2017 poll found that women are much more likely to experience adverse psychological impacts from online harassment (Banet-Weiser and Miltner, 2016).

The key factors which have led towards online misogyny have been identified by Banet-Weiser and Miltner (2015) as: an outdated view of online spaces such as online games being female free spaces for male nerds; men are threatened by potential economic loss as a result of the apparent feminine invasion

of the online space. There is still a perception of women taking away jobs from men especially in technology fields, recognised as a natural right of men. The critical issue which remains is the non-reporting of such crimes due to negatively impacting factors such as normalisation, fear of not being taken seriously and fear of victim blaming (ibid.)

A comprehensive study of cyber violence and hate speech online against women in the European Union has been undertaken by the European Parliament's Committee on Women's Rights and Gender Equality, published in 2018. The key findings from the report are as follows:

Gender inequality is prevalent in the technology sector and is obvious on platforms and in algorithms, creating toxic techno cultures. The main factors which have contributed to cyber gender inequality and as a result cyber VAWG include the prevalence of anonymity, mob mentality and permanence of negative data with the potential of re-victimisation. Varieties of platforms are used for the purpose of cyber violence and hate speech online. These include social media, web content and discussion sites, search engines, messaging services, blogs, dating websites, apps, comments in media and newspapers, forums and chat rooms of online video games. Online violence can take many forms including sexual harassment, sexual abuse and sexist hate speech with the purpose of discouraging women from public spaces. Legitimation and normalisation of violence against women in the media encourages victim blaming and discouragement of victims' perspectives.

Council of Europe (2018) has captured forms of cyber violence succinctly in the following figure.

As seen in the figure above, cyber violence is a dark side of the Internet. It takes multiple forms from doxing (which is identifying private information about an individual with intent to cause harm) to harassment which covers some very serious issues including revenge porn and issuing threats of violence. Cybercrime is recognised as a category of cyber violence as well as hate-based crimes. In some instances, ICT related acts can be transferred to the physical world resulting in serious crimes including kidnapping, torture, damage to physical assets and other actions against an individual.

Figure 1. Forms of cyber violence

Source: Council of Europe (2018)

Actions which would be considered as cybercrime, which is a step beyond cyber violence have been recognised recently by the European Parliament. Recognition of the large list of actions considered as cyber violence is a strong indication that cyber violence is being seriously considered by governments to undertake steps against in the form of legislation to “punish” acts of cybercrimes. European Parliament (2018) has provided a complete coverage of the types of cybercrimes undertaken against women as:

Violations of Privacy: Revenge porn or image based sexual abuse/ exploitation, creep shots, up skirting or digital voyeurism (the taking of non-consensual photos or videos of women’s private areas and sharing them online,

Doxing: Manipulating and publishing private information without consent,

Impersonation: Stealing identity to threaten or intimidate or to discredit/ damage an individual’s reputation,

Hacking: Intercepting private communications and data for example through webcam hacking.

Cybercrimes Also Include Stalking: Cyber stalking is defined as the action of spying, fixating, compiling information to communicate with individuals against their will.

Harassment which includes cyber bullying is defined as the repeated behaviour using textual or graphical content to frighten or undermine someone’s self-esteem or reputation;

Other Forms of Cybercrime Include Threats of Violence: Rape threats, death threats against the victim, their family members or inciting to physical violence, sending victim unsolicited explicit materials or mobbing: which is defined as choosing or targeting an individual to bully or harass through mob (which includes many individuals) deployment.

Cybercrime has been identified to also include Sexist hate speech which is the use of expressions which spread, incite, promote or justify hatred based on sex. This category also includes posting and sharing of violent content, portrayal of women as sex objects or targets of violence, use of sexist and insulting comments, pushing women to commit suicide in some instances.

Direct violence can also emanate from cyber violence and includes trafficking which is the recruitment and luring of women into prostitution through technology, and the use of stolen graphical content to advertise for prostitution. Sexualised extortion refers to identity theft resulting in physical abuse. And online grooming is the setting up of an online abusive relationship with a minor to bring the child into sexual abuse or child trafficking.

Cyber VAWG and Social Media

There have been numerous criticisms against popular social media platforms such as Facebook for not taking proper action against perpetrators of cyber violence especially in countries such as India where the degree of sexual abuse online and in the real world reaches high levels against vulnerable women and children (Safi, 2017). A report titled “Toxic Twitter” published in 2018 by Amnesty International highlighted the issue that in spite of policies and executives’ concerns Twitter still remains a threatening place for women due to its immediate and direct contact between many users and due to anonymity being its key feature (Amnesty International, 2018).

The attack by bots on women through Twitter is another issue that has been identified (Washington Post, 2018). A well-known example of online hate demonstrated via Twitter was against feminist campaigner and journalist Caroline Criado-Perez (Hardaker and McGlashan, 2016). Criado-Perez’s petition to the Bank of England asked to have Elizabeth Fry’s image on the 5-pound note to be replaced by that of another woman and not Winston Churchill’s as planned (ibid). Criado-Perez faced misogynistic abuse on Twitter. As Hardaker and McGlashan (2016) have found, this case demonstrates the construction

of alternative identities through computer mediated communications as well as social experimentation through cyber misogyny (Baker, 2001). The social experimentation with misogyny which results in harm to others without consequences and accountability utilises the availability of anonymity online.

Anonymity can encourage attitudinal polarisation and a higher likelihood of acting on normally inhibited impulses referred to as deindividualization (Siegel, Dubrovsky, Kilesler and McGuire, 1986). Vinagre (2008) has further classified the misogyny related deindividualization as toxic dis-inhibition. Toxic di-inhibition is demonstrated through rude language, harsh criticisms, anger, hatred, threats, pornography, crime and violence. Harder and McGlashan's (2016) twitter account analysis revealed that sexual aggression (sexist abuse and rape threats) was specifically targeted against women. Men were in most instances constructed as makers and senders of rape threats through social media.

Cyber Violence- Impacts and Consequences

As far as the profiles of women who are specifically targeted online are concerned, the report (European Parliament, 2018) found that young women with intersecting identities are the main targets of online hate crimes as well as women who assert their views online and women in power. Cyber-crimes against women have long term psychological, possibly physical as well as economic impacts for the women, their families and for communities (ibid).

If cyber violence actions remain unaccountable for, without serious consequences for the perpetrator, cyber violence has the potential to create not only serious psychological harm for victims but also negative impacts on *gender equality in virtual and physical environments*. For example, there is currently a dearth of female politicians especially female politicians with inter sectionality characteristics in numerous parts of the world including in economically developed countries such as the United Kingdom. Yet the misogynistic culture of the online environment including its dominance in the social media environment poses a major threat to the progression of women in politics. Cyber-crimes such as harassment, racism and death threats pose a very serious issue of excluding women from a critically impacting and decision-making environment which is also a powerful environment with national and international impacts (Messenger, 2017).

A comprehensive global study on the economic impacts of cyber VAWG has not been undertaken yet but there have been studies on the loss of human capital due to gender inequality to which cyber VAWG contributes immensely. This loss has been estimated at \$160.2 trillion which is twice the value of GDP globally (The World Bank, 2019).

Legal Stance Against Online Misogyny

There have been numerous criticisms of policies and legislations' lack of addressing of online misogyny which has the potential of serious social and economic negative impacts and consequences. Shariff and Eltis (2017) have highlighted the issue of the reluctance of higher education institutions for example not including online forms of sexual violence in the institutions' sexual violence policies. This is in spite of the general trend of millennials and GenZ members being regular users of social media. Shariff and Eltis (2017) have emphasized that the legal system (in this case in the context of Canada) is struggling with how to deal with cases of online sexual violence and that victims do not have trust in the criminal justice system. There is also a serious issue of the legal system assigning blame (by police, prosecutors, defence council and in some instances by judges) to the victims.

Developments in the Legal Systems in Multiple Jurisdictions to Address Online Misogyny

As far as developments in legal systems are concerned, they are still in very early stages. Cyber VAWG presents much more complexity to hold individuals/ parties accountable for cyber VAWG. Different types of resources are required to firstly identify perpetrators. There is a general conception that acts of cyber VAWG can be carried out under the veil of anonymity, without the risk of being identified. There are numerous, complex steps which are required to ensure anonymity online. Otherwise, with the undertaking of big data analysis, by assigning characteristics to individuals, and by combining data available for example profile data on social media, data scientists have been able to accurately (by 90 per cent) identify individuals.

The key factor here is whether resources will be assigned such as paying data scientists to identify perpetrators of cyber VAWG. If cyber VAWG is criminalised formally, then such steps would be required. Regions with considerations for legislation to address cyber VAWG have been identified in literature. They mostly focus on online sharing of images without consent but cyber VAWG legislation is still under development in most parts of the world. Based on the extensive Google search undertaken based on keywords of cyber VAWG (and other associated terms) legislation, multiple regions have been covered. The regions selected are based on the methodology employed by The Guardian for its *Web we want series* investigating the dark side of the Internet (Lyons et al. 2016). Regions prominently covered in other media and reports are also addressed. The following regions are provided as examples where legislation is present or where it is not in existence yet, to address cyber VAWG. Based on this analysis it can be assumed that in spite of the increasing prevalence of cyber VAWG for example in countries like India or China, legislation to address this issue is not comprehensive enough to tackle cyber VAWG effectively. It is important to understand that cyber VAWG legislation is different from VAWG legislation. Multiple countries have legislation to prevent violence against women and girls for example to stop genital mutilation, or sexual harassment in public spaces but cyber VAWG is not addressed by these legislations.

Europe

The Council of Europe (COE) Parliamentary Assembly has recognized the serious negative consequences and impacts of online hate and violence. Resolution 2144 (2017) on ‘Ending cyber discrimination and online hate’ has recognised that sexism and misogyny are types of hate speech and are unacceptable. COE member states have been encouraged to ensure that legislation covers all forms of online violence against a person or a group including the full range of characteristics considered as grounds of protection under discrimination law (Jurasz and Barker, 2017). The Council of Europe has also recognised online misogyny as a major hindrance against the objective of achieving gender equality and has recognised the tackling of cyber gender violence as a key priority (Council of Europe, 2016).

United Kingdom

In the United Kingdom Malicious Communications Act 1988 implies criminal liability for the sending of offensive communications where there is an intention to cause distress or anxiety. It's the application of the Act and the very low percentage of criminal liabilities imposed as a result of cyber violence which has been raised as a serious issue. One of the issues is the degree of thresholds which are applied to recognise an online communication as either abuse or a hate crime (Jurasz and Barker, 2017). Recently, the Law

Commission in the U.K. has stated that the law has failed to keep pace with the dramatic shift in the way society now communicates through online mediums including social media which has brought with it the potential for harm and offence on a massive scale (Hymas, 2018). The Commission has recognised that women are most impacted with misogynistic abuse. The Commission has recommended that online criminal behaviour should be treated the same as in the physical world. And that law for malicious (for example hateful) communications is still ambiguous and needs to be reformed for the purpose of clarity, understandability and effectiveness (Hymas, 2018).

Scotland (Source: Jurasz and Barker, 2017)

Section 127 of the Communications Act 2003 (applicable in Scotland) implies criminal liability for an improper use of a public electronic communications network. Prosecutions made under this provision deal with messages or other matters that are grossly offensive or of an indecent, obscene or menacing character. The section also covers instances of an offence to send or cause to be sent a false message for the purpose of causing annoyance, inconvenience or needless anxiety to another individual.

According to Jurasz and Barker (2017) online text-based abuse should be included in legislation as a criminal offence to reflect other forms of online abuse including image-based sexual abuse. In the context of Scotland, this would imply an amendment to the Abusive Behaviour and Sexual Harm (Scotland) Act 2016. The authors submitted this recommendation to Scottish Parliament's Public Audit and Post-Legislative Scrutiny Committee.

United States

In the United States, Violence against Women Act was passed in 1994 and was further expanded on in the International Violence Against Women Act (I-VAWA), introduced in the U.S. House of Representatives in February 2018 and faces the risk of lapsing in 2018 (Washburn, 2018). The Act has laid the foundations for the Interstate stalking statute and VAWA includes a cyber-stalking provision which can be used against cyber bullying, extortion, defamation, threats, spying, murder, death, serious body injury resulting from digital harassment, surveillance or intimidation (Parra, 2015). The complexities associated with the legislation and the lack of prosecution against online harassment makes it difficult for victims to seek justice in the United States (Carpentier, 2016). There is also a level of ignorance faced by police regarding the serious impacts of cyber VAWG and the civil process ends up being expensive and time consuming to address online harassment (Sweeney, 2014).

Canada

Bill C-13 has been introduced which makes the distribution of intimate images without consent on the Internet a criminal offence (Broadband Commission for Digital Development, 2015).

China

There is no formal legislation to address cyber VAWG in China at present, in spite of it being highlighted as a growing and serious issue for Chinese youth (Lyons and Phillips, 2016).

India

The Indecent Representation of Women (Prohibition) Act 1986 prohibits the indecent representation of women through advertisements, publications, writings, paintings, figures or in any other manner. Any person who violates the provisions of this Act is punishable with imprisonment for a term of two years on first conviction and in the event of subsequent conviction, the imprisonment may extend to five years. To widen the scope of this Act, changes suggested by the National Commission for Women are being examined by the Ministry of Women and Child Development (MWCD) (UN Women, 2016).

The Indecent Representation of Women (Prohibition) Bill 2012 extends the emphasis on portrayal of women in electronic media and electronic modes of distribution of materials. There has been criticism of the term decency and its application in the context of cyber VAWG. At present indecent representation of women is defined as the depiction of the figure or form or body or a part of it of a woman in a way that is indecent, derogatory or denigrating or is likely to deprave, corrupt or injure public morality (Rajagopal, 2017). This definition has been criticised for its ambiguity and more precise understanding of online occurrences, resulting implications of cyber VAWG, including punishments have been asked for.

Russia

Online trolling, especially to promote the government's agenda and to harass anyone trying to stand against the government and authorities as well as to subdue human rights activists is a widespread occurrence in Russia. Gay rights activists are specifically targeted in Russia in the cyber space (Walker, 2016). Understandably, there is no formal legislation for protection against cyber VAWG in Russia.

Colombia-South America

Colombia has had a deep rooted culture of machismo, which rewards hierarchical notions of gender and traditional family roles (Lyons and Phillips, 2016). As a result NGOs especially feminist groups are harassed and threatened not only in the cyber space but also in the physical world. Threats in a lot of cases are followed by physical harm such as sexual assaults of females involved in campaigning for women's rights.

Australia

In Australia, serious cases of abuse through Twitter and Facebook have been punished under the Criminal Code which makes it illegal to menace, harass or threaten through various communications mediums (Farrell, 2016). Two states in Australia, have introduced laws to criminalise the sharing of intimate photos without consent and there has been a Senate committee recommendation to make this a Federal Law.

The Republic of Congo: Africa

Online harassment, cyber VAWG, is not taken seriously in Congo. Females are usually reluctant to report any incidents, yet cyber VAWG is prevalent in the country as is victim blaming (Lyons and Phillips, 2016). Bribery and corruption are also identified as serious issues which act as a barrier to accountability for cyber VAWG in the country.

Summary of Legislation Powers

Based on the analysis above, it appears that in most parts of the world legislation is currently lacking to address cyber VAWG. Even if legislation exists, the complexity of the legislation for example relating to how online communications are treated (harassment versus bullying versus abuse for example) lead towards legal complexities in the court room which can discourage victims of cyber VAWG to report incidents. As literature suggests, victims do not feel confident that bringing to light incidents of cyber VAWG will have any material impact. As the statistics suggest the number of legal cases and the seriousness of punishment for cyber VAWG seem minimal and have been criticised as not being serious enough.

Another issue that has come to light is the lack of awareness and training for law enforcement bodies, which have been grappling with ways to handle situations relating to cyber VAWG. Communications between law enforcers and victims of cyber VAWG have not been perceived as supportive and understanding of the experiences which victims of cyber VAWG have faced. Never the less, international organisations such as the United Nations and UNESCO have provided detailed recommendations to address cyber VAWG.

SOLUTIONS AND RECOMMENDATIONS TO IMPROVE CYBER VAWG RESPONSE

UNESCO (2015) has made the following recommendations for action against cyber VAWG:

Based on the finding that law enforcement agencies and the courts are failing to take appropriate actions for cyber VAWG in 74% of 86 countries surveyed and due to lack of reporting as a result of fear of social repercussions in countries rife with cyber VAWG UNESCO has recommended rigorous oversight and enforcement of rules banning cyber VAWG on the Internet. UNESCO has also, pushed for recognition by governments, regulators, businesses and Internet users that an unsafe Internet implies that women will use the Internet less freely, resulting in costly societal and economic implications. Also, that there needs to be the recognition by internet and social media providers (industry players) of the important role that they play as digital gatekeepers. Industry players include ISPs, mobile phone companies, social networking sites, online dating and gaming sites, website operators and software developers. Tech companies, also as an important industry player, need to recognize cyber VAWG as unlawful behaviour, and need to demonstrate cooperation in providing relief to victims/survivors. They need to focus on better systems for cooperating with law enforcement, more effective takedown procedures for abusive and harmful content, they need to undertake serious consideration of account termination for misconduct and they should produce transparent reports of records specific to cyber VAWG, detailing how and when they have responded (UNESCO, 2015). UNESCO has proposed the three S's which need to work in conjunction with each other: Sensitisation which implies the promotion of changes in social attitudes, Safeguards which cover oversight and monitoring to minimise risks and Sanctions which imply the adoption and application of laws and regulation against cyber VAWG.

Sharriff and Eltis (2017) have suggested that higher education institutions should partner with the justice system, and social media providers and engage the power of students' social media expertise to educate, and sensitise all relevant stakeholders including law enforcement officials. The authors have also recommended raising the standards of online speech and social media activities and recognising online sexual violence as an important element of higher education institutions' sexual violence prevention policies and responses.

The U.K. Government's 2016-2020 strategy has provided this response to addressing cyber VAWG: to address cyber-enabled VAWG by working with the police led Digital Intelligence and Investigation Programme to promote improvements in police capability to investigate online VAWG offences (HM Government, 2016).

European Women's Lobby's (2017) recommendations to address cyber VAWG include:

Policy responses to recognise that cyber VAWG is a type of violence against women and to capture voices of women who are victims of cyber VAWG,

An aim of EU and member states to agree on definitions of forms of cyber VAWG and as a result to include all types of cyber VAWG in legislation As well as to ensure victim access to justice and support services,

Development of legal instruments and policy strategies to punish online VAWG,

An EU Directive and other measures specifically aimed towards addressing VAWG,

To promote improvements in gender dis-aggregated data (including information on sex/gender of the victim, the perpetrator and the relationship) with a focus on the impacts of cyber VAWG, and creating data on the effectiveness of interventions.

Provide support services specifically dedicated to protect women and girls from online violence,

Sustainable funding for such initiatives,

Criminalisation of cyber VAWG,

Training of police, justice systems and professionals to detect, respond and prosecute cyber violence,

The establishment of an independent entity to hear and decide on cyber VAWG cases,

Perpetrators and re-transmitters to be held responsible as well as business entities to respect and remedy human rights through operations,

Internet intermediaries to be held responsible to ensure that platforms are not abused to initiate or maintain cyber violence.

The organisation has also provided recommendations for preventative measures including: adoption of self-regulatory standards to help avoid harmful gender stereotyping and the distribution of degrading images of women or sexual violence imagery. There is also an emphasis on tech companies and internet providers to implement a code of conduct, and gender diversity and equality in the media industry as well as gender training. Also to critically evaluate media information is also proposed. Pornography has been proposed to be recognised as a form of male violence and that opt-in filters should be made available by all internet providers and it is proposed that legislation should limit the distribution of online pornography.

Key action and steps that can be undertaken to tackle cyber VAWG include: development of international policy to recognise cyber VAWG as a crime, to develop international standards to address cyber VAWG through law enforcement agencies as well as greater transparency around cyber VAWG. Transparency should encourage victims of cyber VAWG to report incidents of cyber VAWG to law enforcement bodies and social media platforms should encourage reporting of cyber VAWG. Awareness and education programs need to be undertaken with a specific focus on cyber VAWG, targeting young men and boys to influence behavioural change. Respect in communications can be one element that initiatives around education and awareness can encompass. Education around breaking away from stereotypes of women as sexual objects, weak, something that can be easily abused or men being the more powerful gender (misogynist stereotyping) is critical to implement change towards addressing cyber VAWG.

FUTURE RESEARCH DIRECTIONS

This chapter has laid the foundation for understanding cyber VAWG. It has also provided a brief understanding of the impacts of this cybercrime as well as the legal stance on cyber VOWG. Future research should look at evaluating actual changes which are taking place in legislation, in enforcement mechanisms and expert views on whether these measures are adequate or whether they require further action and the types of strategies which can be adopted. Types of social changes which need to occur but are hard to implement in this space need to be evaluated, also from organisations and systems perspectives. There is a very large potential in this space for further research, also from country and jurisdiction specific perspectives.

CONCLUSION

Cyber VAWG is a recent phenomenon, allowed by affordance of misogynistic behaviours through the Internet; which has potentially serious implications including the extension of online violence to the physical environment. It is the case of online misogyny which jurisdictions around the world are trying to firstly accurately define and secondly aiming to create adequate legislation and its enforcement to address. As demonstrated in the multi-regional coverage of legislation, legislative developments against cyber VAWG are still in infancy or do not exist in many countries.

There is a large amount of work which needs to be undertaken to tackle cyber VAWG, at various levels of legislation development, enforcement and social change. A critical issue which needs high level (international) attention is the risk and danger which online misogyny poses from various perspectives including the exclusion of females from the Internet. Internet is a powerful instrument of communication and change and tackling online misogyny is an important factor towards promoting gender empowerment and promotion of human rights online. As discussed above there are various recommendations which have been provided but it is their actual implementation in the form of action for example in the form of punishment for online misogyny or social media providers' implementation of a code of conduct which need to occur. Implementing accountability to tackle cyber VAWG and to make the internet a safe space is critical for female empowerment and gender equality in the Internet environment.

Intimate Partner Cyber Abuse Viewed Through the Lens of Criminology

Curtis L. Todd

Atlanta Metropolitan State College, USA

Joshua E. Byrd

American Intercontinental University, USA

Leroy Baldwin

Atlanta Metropolitan State College, USA

INTRODUCTION

The field of Criminology covers all areas of criminal justice systems – law enforcement, the courts and corrections. Governing policies and protocols of these coordinated networks, from controlling crime, adjudication to imposing penalties on those who violate laws, are often informed by social scientific inquiry and have far reaching implications beyond academia.

Intimate Partner Cyber Abuse is an area that should now figure prominently, not only as a research target among criminal justice scholars, but also among practitioners. It is the new looming frontier that local, state, national and international criminal justice jurisdictions and other stakeholders grapple with in efforts to effectively hold offenders accountable and to support victims of this kind of abuse being perpetrated via technological structures. The pervasive and anonymous nature of the Dark Web fosters the ideal environment where Intimate Partner Cyber Abuse can go undetected due to the absence of standard regulatory oversight and laws.

In addition to confronting this emerging frontier, there is a need to interrogate the crevices between where criminal justice systems are – with respect to Intimate Partner Cyber Abuse – and the advances that need to occur to ensure appropriate and effective responses across all systems. To that end, the purpose of this chapter is to significantly assist in filling these problematic gaps. Key concepts are first contextually defined to establish a clear understanding of the complex issues associated with Intimate Partner Cyber Abuse. Additionally, gateways to abuse and exploitation, as well as protective strategies, and inherent implications are examined to fully explicate the importance of refocusing this issue through a criminological lens. Data and relevant literature are also mined to provide thoughtful and robust suggestions and recommendations. Finally, future research directions are presented.

BACKGROUND

Criminology is the scientific study of how laws are made, those who break them and how the criminal justice system responds to them (Sutherland & Cressey, 1960). The landscape it examines has grown exponentially since the inception of the internet. With this expansion has come new tools for criminality and new ways in which crime and violence can occur. The unprecedented growth which has taken place

DOI: 10.4018/978-1-5225-9715-5.ch041

on the World Wide Web has given birth to a digital Pandora's Box called the Dark Web, where many facets of cybercrime, such as violence and victimization, occur at alarming rates which includes cyber abuse among intimate partners. In simplistic terms, the Dark Web can be defined as the problematic facet of the Web associated with cybercrime, hate, and extremism (Fu, Abbasi, & Chen, 2010). The undetectable and often impenetrable nature of the cyberspaces where these crimes occur are referred to as "the deep web" and it is here where cybercriminals identify their targets and carry out their unlawful agendas. The complexities associated with this new terrain has created a "perfect storm" that has yet to be fully understood. Moreover, these challenges have brought with them new predatory criminals such as cyberbullies and abusers. New criminals who launch attacks from cyberspace are technologically savvy and seemingly operate in a world where laws and meaningful oversight have not kept pace with the rapid growth of the web, nor the myriad of ways in which it has been weaponized to advance personal, social, political and economic agendas. They use the far-reaching tools of the digital world to exact violence upon their victims whether they be strangers or intimate partners.

INTIMATE PARTNER CYBER ABUSE

The operational definition of Intimate Partner Cyber Abuse is framed through a bifurcated lens that explicates the terms "intimate partner" and "cyber abuse." The Center for Disease Control and Prevention, National Center for Injury Prevention and Control's publication "Intimate Partner Violence Surveillance: Uniform Definitions and Recommended Data Elements, Version 2.0," which was authored by Breiding et al (2018) endeavored to promote, as well as improve consistency in which Intimate Partner Violence is surveilled across organizations and among stakeholders seeking to address this problematic social issue. The definition of intimate partner, among other critical descriptions included in the publication, notes:

An intimate partner is a person with whom one has a close personal relationship that may be characterized by the partners' emotional connectedness, regular contact, ongoing physical contact and sexual behavior, identity as a couple, and familiarity and knowledge about each other's lives. The relationship need not involve all of these dimensions (p. 11).

Further, a defining feature of intimate partner includes current or former relational characterizations such as spouses, boy and girl friends, dating partners or ongoing sexual partners. They can be in an opposite or same sex relationship. They may be living together or not. It is also important to note that an intimate partnership need not require sexual intimacy (Smith, et al, 2018).

Intimate abuse, due to its seriousness, is frequently captured in the literature alongside the terms such as intimate violence, relationship violence, and domestic violence. Therefore, to further operationalize Intimate Partner Cyber Abuse, the definition of abuse is drawn from a seminal report by the Working Group on Intimate Partner Abuse and Relationship of the American Psychological Association. The Group (2002) concluded:

Abuse usually includes an ongoing pattern of behavior, attitudes, and beliefs in which a partner in an intimate relationship attempts to maintain power and control over the other through the use of psychological, physical and/or sexual coercion. Abuse usually produces fear and trauma in those being victimized, whereas isolated aggressive acts may not (p.3).

Therefore, Intimate Partner Cyber Abuse is characterized by online behaviors that threaten, intimidate, harass, humiliate or harm a person involved in a close personal relationship with another person in which they are described as being a couple due to their relationship meeting certain conditions such as emotional connection, regular contact, and ongoing physical contact that need not be sexual.

It was only a matter of time before social interaction in virtual landscapes would evolve into intimate partnerships. These cyber relationships present a myriad of opportunities when they escalate into abuse perpetrated either exclusively online or in the physical world. At times, the impetus and continuation for some of these relationships is fraud, and has become known as Online Romance Scams (Whitty & Buchanan, 2012). Another form of fraud that has increased over the years in an activity known as “catfishing,” which involves perpetrators posting false information, profiles, and at times photographs, with the sole purpose to intentionally manipulate, mislead, or harm others. Unfortunately, computers and technological advances have afforded growing avenues and opportunities for abuse to include cyber exploitation, intimidation, stalking and psychological aggression. Due to easily acquired levels of anonymity, the capricious nature of cyberspace and perpetrators not needing a geographical locale, variances in Intimate Partner Cyber Abuse easily expands in its frequency and severity.

For the purpose of this chapter, Intimate Partner Cyber Abuse, focuses on relationships that are initially forged online and the abuse is perpetrated via technological structures and social media networking platforms to include email, apps, twitter, instagram, snapchat, tumblr and the like. The definition is inclusive of relationships that transitions to the physical world. Further, a rise in what is being referred to as digital domestic violence and digital abuse is now on the radar. This abuse also includes the use of texting, as well as smart technology such as internet-connected locks, thermostats, lighting and cameras through smartphone apps connected to internet-enabled devices (Bowles, 2018). All of these acts are meant to further harass, monitor, and control intimate partners. Caution must be also taken not to be dismissive of other digital landscapes in which abuse could occur which might be evolving or existing in the margins, away from mainstream online platforms.

Gateways to Cyber Abuse

The term ‘gateway’ has been traditionally associated with drugs usage and the theory that such use increases the probability of the user engaging in other further drugs. The ideology is also analogous to marijuana being designated as a gateway to more dangerous drugs, therefore protective factors need to be strengthened and risk factors mitigated as it relates to cyber abuse, generally and specifically among intimate partners. Numerous pathways lead to the Dark Web, “Big Box” websites and social media platforms provide the nexus which links users of all ages to a frontier society eerily similar to the days of the “wild west” in the western world, where law enforcement was virtually nonexistent and occurrences of violence and crime were abundant. It is within this framework that well intended users who hold naive assumptions learn to navigate this burgeoning digital world which seems to find a way to entangle all who enter.

Within moments of visiting “Big Box” social media platforms, like Facebook and Instagram, then establishing a user profile and going live with their account, members of cyberspace can quickly find themselves in an unintended relationship. Beginning with the preverbal “handshake” which is achieved by liking a post, picture or video, intimate relationships in cyberspace quickly progresses. In the cyber world, liberal norms mixed with a lack of professional digital decorum, ultimately mold relationships into unrealistic, unattainable and oftentimes deceptive illusions, almost from their inception. The creation

and evolution of these relationships often move as fast as the high speed digital highway will allow, advancing the stages of such relationships by the click of a mouse.

Protective Strategies

Protective factors or strategies is a wide-ranging catchphrase used to advance the idea that informed and planned measures can be employed to prevent the occurrence of an undesired outcome. To that end, various tactics have been suggested to address the dangers of interacting with others in cyberspace, but without comprehensive solutions comprised of international alliances, the prospects of curbing instances of Intimate Partner Cyber Abuse and related violence show little promise. Some promising well intended efforts are underway, but to be effective, the strategies employed should be inclusive of fair and balanced frameworks. Such measures should also be lenient, flexible enough to provide space for free communications and rigid enough to protect the interest and safety of would be cyber abuse victims. In North Carolina, courts decided the state went too far in addressing cyber violence when it enacted a 2009 law focused on curbing cyber bullying. They argued the law reached too far in prohibiting certain uses of computers and that would encourage or show purposeful intimidation of others online.

Other efforts can be seen internationally. Consider China as a case study. In China, nearly every digital interaction is captured and stored in a database linked to an individual's social credit score. This database, one of the largest social engineering projects ever attempted, aims to monitor the actions of China's entire population, over a billion people, by maximizing the technological advances of the internet and its tools. The success of China's system has yet to be determined; nevertheless we know that China's approach, though well intended, may go too far in restricting personal freedoms in other countries.

Macro level approaches to address Intimate Partner Cyber Abuse may also serve as successful strategies. In the United States, the Centers for Disease Control and Protection (CDC) recommends teaching healthy relationship skills as a means of reducing risk and incidences of intimate partner abuse (Centers for Disease Control, 2017). Similar recommendations have also been suggested in Canada where teaching basic behaviors like respect and responsibility have been offered as strategies to protect children from cyber abuse (Broll 2018). A public health approach, which focuses on harm prevention and reduction by identifying risk and protector factors, has immense currency in safe guarding individuals and the larger society against someone becoming a victim or a perpetrator of Intimate Partner Cyber Abuse.

Protection Orders and Other Legal Remedies

Employing legal avenues as a response to cyber abuse can be expensive and time consuming. However, it is an important step that needs to be taken in holding perpetrators accountable. Further, legal remedies also offer a measured attempt to reclaim ones dignity, value as a human being and engenders a sense of empowerment. Traditional protection efforts are found in instances of domestic violence with attempts to remedy abuse through the following: Emergency Protection Orders, Protection Orders and Restraining Orders. An Emergency Protection Order can be given by a police officer in some states. The Order, which is generally limited to no more than a week, is given when the abuser is arrested for domestic violence. It is also typically given by a magistrate. A Protection Order ranges from one to five years and can last up to a lifetime. This type of protective order can be found in each of the 50 states in America, as well as in the District of Columbia. There are also different provisions in a Protection Order such as no contact, move out and in some cases a counseling provision. Last, a Restraining Order differs from the aforementioned orders in that it requires individuals in a lawsuit to do or not do certain

things, usually stemming from case related situations such as divorce, civil or other family cases (Find Law, 2018). When Intimate Partner Cyber Abuse is perpetrated, these efforts can fall short as protective legal remedies against abuse because they do not go far enough in covering potential acts executed via technological structures.

While every case of Intimate Partner Cyber Abuse is different, seemingly, there has been a near collective effort in the United States to address the issue of revenge porn, also known as nonconsensual pornography, which is among the most deleterious type of cyber abuse. Forty states and the District of Columbia now have revenge porn laws (Cyber Civil Rights Initiatives, n.d.). Some states have measures that include specific language such as cyber harassment statutes, cyberbullying policies, cyberstalking, harassment by telecommunication device, state online harassment, obscene electronic communications, computer crime, and harassment by computer laws. Other state laws have attempted to cover acts like revenge porn under existing harassment statutes.

SOLUTIONS AND RECOMMENDATIONS

As with most crime, addressing criminality such as Intimate Partner Cyber Abuse is a moving target that keeps pace with technological advancements in cyberspace. The nature of these changes and the continued growth of internet users, websites, apps and messaging platforms make it nearly impossible for law enforcement to sufficiently address this crime and hold criminals accountable for their abuse. There are however, strategies that can be implemented which may prove successful in decreasing the prevalence and pain resulting from such abuse and proposed processes for resolutions to make abuse victims whole. In addition to not sharing private data and reporting instances of abuse, the following proposed recommendations go above and beyond common best practices for internet users.

- Define and elevate Intimate Partner Cyber Abuse to priority status to be addressed by politicians, practitioners, police and private citizens.
- A robust research agenda needs to be developed to investigate the prevalence, correlates, and consequences of Intimate Partner Cyber Abuse, nonconsensual pornography and other related abuses (Eaton, Jacobs, & Ruvalcaba, 2017).
- Create international legal frameworks as recommended by the American Civil Liberties Union (ACLU) and other free-speech groups devoted to providing uniformity of cyber laws aimed at penalizing those who post false information via digital tools and techniques to intentionally manipulate, mislead, or harm others.
- Hold Internet providers accountable for providing strict account authentication procedures for those who use their services and require account holders to follow specific rules while using the internet.
- Require mandatory cyber training for law enforcement personnel and educators which also focuses on Intimate Partner Cyber Abuse.
- Provide more efficient methods of approving video and photo uploads to minimize the psychological harm inflicted upon those who approve the publishing of online videos and photos such as what was referenced in “The Cleaners,” a documentary film that addressed the psychosocial harm suffered by employees who monitor, sift through and remove inappropriate content on the Internet for “Big Box” social media networks.

- Create a credit scoring system for online behavior similar to China's new Social Credit System. Just as an individual's personal credit score can fluctuate depending upon their business relationships, a person's social score should adjust similarly in response to their online behavior. For example, a person's social credit score would decrease if they are found guilty of posting fake news online, catfishing or cyber abuse.

Finally, there is an overwhelming need to also educate national and international groups that occupy influential spaces regarding the presence and rise in this type of abuse. Criminal justice system networks must remain proactive, rather than relying on reactive posturing as it relates to legal remedies. Greater effort is needed in educating individuals of their rights and applicable laws when they have been abused. This can be achieved through Intimate Partner Cyber Abuse awareness campaigns from victim assistance programs, advocacy groups and public service announcements across all media platforms, especially the web, which is "ground zero" for this issue.

FUTURE RESEARCH DIRECTIONS

The colloquial expression, "the train has left the station," is instructive when considering the breadth and depth of exploration needed to fully realize current and future issues related to the varied aspects of cybercrime. It is a new frontier and Intimate Partner Cyber Abuse figures prominently. The following recommendations for future research directions, though not exhaustive, provide a thoughtful thematic structure and agenda useful in closing gaps regarding where we are and where we should be to effectively address Intimate Cyber Partner Abuse.

- Greater gatekeeping measures need to be comprehensively examined in efforts to provide informed prevention strategies to counter predatory and abusive behavior.
- Research initiatives must specifically target cyber monitoring practices pertaining to "age related" and "time spent online" behavior as a means to protect vulnerable populations.
- Cyber privacy and protection can be strengthened through social scientific research and can garner additional policies, procedures and protocols useful for the public and private sectors.
- Ongoing methods to determine the effectiveness of existing laws must include longitudinal studies. A review over time has immense utilitarian purposes in determining what is and is not working to counter cyber abuse.
- Scientific inquiry that explores the role of criminal justice systems (law enforcement, courts, corrections) and their response to cyber abuse should be an ongoing endeavor to ensure updated and relevant information and practice standards.

CONCLUSION

There is an abundance of research on the harmful nature of intimate partner abuse and its impact on those victimized by offenders. Further, though best practice standards in assisting abuse victims continue to evolve, there is much more work to do in our understanding of this issue and ability to appropriately address the social, emotional and psychological impact of Intimate Partner Cyber Abuse. Understanding the complex nature of this type of abuse is an important first step in providing holistic remedies. Criminal

justice educators, researchers and practitioners are uniquely positioned on the frontline of identifying problematic and criminal behaviors, proposing solutions and recommendations, as well as directing future social scientific inquiry. Intimate Partner Cyber Abuse is now on our collective radar and its impact on individuals cannot be minimized. As the digital world continues its rapid expansion, keeping pace with it must be matched with aggressive strategic measures from criminal justice networks, both nationally and internationally. This includes robust examination and monitoring of technological gateways that lead to abuse, as well as developing protective strategies informed by research. Finally, within the same mindset, legal remedies and provisions must not be allowed to wane or lag. The assertiveness that is being employed by intimate partner cyber abusers must be met with the full authority of criminal justice systems which are committed to conquering this new frontier that also ensure that survivors, as much as possible, are made whole.

KEY TERMS AND DEFINITIONS

Catfishing: Using digital tools and techniques to post false information, profiles, and or photographs with the sole purpose of intentionally manipulating, misleading, or harming others.

Criminology: The critical and systematic examination of how laws are made, the means, modes and motives of criminal offenders, and the collaborative responses to criminal activities by the judicial system, policy makers and community stakeholders.

Cyber Abuse: Online behavior that threatens, intimidate, harass, harm, or humiliate a person.

Cyberbullying: The act of bullying by employing tools available on electronic devices which connect to the internet, messaging services, and others digital communication networks.

Cybercrime: The violation of law on internet platforms (or in cyberspace) by incorporating internet tools and electronic devices such as phones and computers.

Dark Web: Areas in cyberspace operating outside of the purview of law enforcement and internet regulations which provide ample opportunities for digital criminal enterprises to exist.

Gateways to Cyber Abuse: Computer applications or apps, websites, social media networks, texting services and other communication modes which can digitally or electronically connect users to cyberspace (the internet).

Intimate Partner: A close personal relationship between individuals who identify as a couple that is characterized by some of the following dimensions: emotional connection, regular contact, and ongoing physical contact that need not be sexual.

Nonconsensual Pornography: The distribution of sexually graphic images, including through digital platforms, of individuals without their consent. This is also referred to as “revenge porn,” “cyber rape,” and “involuntary porn.”

The Dark Side of Engaging With Social Networking Sites (SNS)

3

Eileen O'Donnell*Technological University Dublin, Ireland***Liam O'Donnell***Technological University Dublin, Ireland*

INTRODUCTION

Although engagement with the deep or dark web may seem to some to be intimidating or possibly threatening, the surface web similarly presents users with challenges which may also be detrimental to one's peace of mind or health. This paper reviews the dark side of engaging with the surface web through the use of Social Networking Sites (SNS), the issues discussed in this paper will also be relevant to users' engagement with the deep and dark web. While SNS have the potential to impact positively on adolescent's health and well-being, the use of SNS has the potential for exposure to possible risks (Guinta & John, 2018). SNS include: Facebook (2018), QZone (2018), YouTube (2018), Twitter (2018), Reddit (2018), Pinterest (2018), Tumblr (2018), Flickr (2018), Whatsapp (2018), Snapchat (2018), Viber (2018), Google+ (2018), Instagram (2018), LinkedIn (2018), Skype (2018), Tinder (2018), Grindr (2018), amongst many others used around the world. Computer algorithms are used to draw people in to frequent use of SNS. Once someone is online and engaging with SNS, more computer algorithms are used to keep the persons attention and hence increase the amount of time spent online. Recommender systems are used to enhance collaborative filtering algorithms which encourage users engagement with Social Networking Sites (Eirinaki, Gao, Varlamis, & Tserpes, 2018; Liu & Lee, 2010). The dark side of engaging with SNS includes: addiction or addictive behavior, child pornography, cyberbullying, fake news, Fear Of Missing Out (FOMO), social comparisons, stalking, amongst many others, which can all lead to neglect of other duties, sleep deprivation, loneliness, isolation, depression, and so forth. The aim of this chapter is to review the negative effects of engaging with SNS and consider what solutions can be proposed to alleviate the damage caused by engagement with SNS.

BACKGROUND

"It is increasingly observable that social media present enormous risks for individuals, communities, firms, and even for society as a whole" (Baccarella, Wagner, Kietzmann, & McCarthy, 2018, p. 431). Now that we as a society are aware of the possible dangers posed by social media, it is time to address all of these potential risks with individuals, communities, organisations, and so forth. By identifying and highlighting these risks and through ensuring that individuals, communities, and organisations are made aware of these risks, only then will it be possible to successfully deal with such risks. "Even with social media executives admitting that their platforms have deleterious impacts, users tend not to question the short- and long-term implications and potential risks of their choices" (Baccarella et al.,

DOI: 10.4018/978-1-5225-9715-5.ch042

2018, p. 432). Users should be encouraged to question the short and long term risks of engaging with SNS. This is a discussion in which all members of society should engage, not just parents and school teachers. Many adults are experiencing problems as a result of excessive engagement with SNS. This paper reviews some of the negative effects of engaging with SNS on the habits (addiction and addictive behaviour, exposure to child pornography, cyberbullying) and mental health (fake news, fear of missing out, social comparisons, stalking) of users. In addition, users are encouraged to consider how their use of SNS may be impacting the lives of others (family members, work colleagues, and other online users).

The Dark Web

The dark web represents a number of anonymously created websites which are hosted on the deep web. The dark web is intentionally hidden (Paul, 2018), the content is not indexed for search engines to find, unlike the surface web where the content is indexed and accessible to standard web browsers, for example, Google Chrome (Google, 2019), Mozilla Firefox (Firefox, 2019), or Microsoft Internet Explorer (Microsoft, 2019). The surface web is the opposite of the deep web (also known as the invisible web and the hidden web). The surface web is easily accessible to all using standard web browsers on the internet. The deep web and the dark web are not accessible through standard web search engines and web crawlers.

In a research study conducted by Dalins, Wilson & Carman (2018) the findings suggest that “criminality on this ‘dark web’ is based more upon greed and desire, rather than any particular political motivations” (Dalins et al., 2018, p. 62). The dark web refers to a number of anonymously hosted websites on the deep web which are accessible by using specialized software to hide the Internet Protocol (IP) address. IP addresses are assigned to every device that connects to the internet. A Public IP address can be accessed over the internet, a Private IP address cannot be accessed over the internet but are used in internal networks. A Global IP address is specific to a particular network and all devices using that network. Internet Service Providers (ISP) assign Global IP addresses.

The dark web is part of the World Wide Web (WWW) that is only accessible through the use of specialized software (Monk, Mitchell, Frank, & Davies, 2018). The dark web is an encrypted network (to enforce anonymity) that exists predominantly between The Onion Routing (TOR) encryption tools, servers, and their users (Monk et al., 2018). Users of the dark web have the option to remain anonymous and untraceable. Methods employed to access the dark web are quite involved therefore the dark web is not used by the average user. “The globalization of technology and rise of popularity in cryptocurrencies has changed the face of black-market trade and the actors that carry out these crimes” (Paul, 2018, p. 1). Law enforcement agencies and Government Departments are continuously playing catch up in trying to deal with innovations adopted by black market traders to conceal the money trail. “The internet provides an ever-growing number of ways to hide, launder money and pursue a vast range of criminal activities in ways that are difficult to detect or deter” (Slaughter, 2018, p. 118). The handling of criminal activities conducted online is challenging, expensive and requires sufficient quantities of technical resources. The dark web can be used for illegal activities, such as: the sale of drugs (Mackey, 2018; Norbutas, 2018; Porter, 2018), firearms (Porter, 2018), untraceable cryptocurrencies such as Bitcoin (Paul, 2018), child pornography (Dalins et al., 2018), trade in exotic animals (Paul, 2018), sale and purchase of credit card details (Hayes, Cappa, & Cardon, 2018), identify theft (Hayes et al., 2018), money laundering (Dalins et al., 2018; Wegberg, Oerlemans, & Deventer, 2018), amongst others. The monetary cost alone of trying to monitor criminal activities that are conducted online puts a burden on law enforcement agencies and Governments. The Silk Road is a dark net market or an online black market known for the sale of illegal drugs (Dalins et al., 2018; Hayes et al., 2018). It is illegal to use websites that engage with illegal activi-

ties. Due to the ubiquitous nature of the WWW and the anonymity provided, the dark web poses serious challenges to law enforcement agencies around the world. Law enforcement agencies can only achieve so much, members of society must be vigilant and mindful of the legality of the interactions and transactions that they conduct online. It is not only on the deep dark web that illegal activities take place, they are also conducted on the surface web, for example, sale of contraband goods, sale of replicas of branded products, sale of government services with an additional administration charge included, and so forth.

Traditional search engines or web browsers cannot access content available on the dark web. This paper reviews SNS that are accessible through the use of traditional search engines on the surface web where the content is indexed and accessible to standard web browsers. The negative effects of engaging with SNS on the surface web also relate to users engagement with the deep and dark web.

Virtual Private Network (VPN)

VPNs can be used covertly to obscure a users' browsing and online activities from prying eyes. Therefore, illegal activities and transactions can be hidden by using VPN transactions. A Virtual Private Network (VPN) enables the user to send and receive data across a public network, as if it were a private network. A Virtual Private Network (VPN) provides a means of connection to a network within an organisation (as if you were inside the organisation) even though you are not physically present. During the online session the connection is made to the remote network (within the organisation) through the VPN therefore none of the devices (printers, shared disks, and so forth) connected to the local network are available for use to the user as long as the user is remotely connected to the network within the organisation.

Figure 1 illustrates a standard connection to a network within an organisation where there is no need for a Virtual Private Network. The users' remote connection to the network of the business or organisation can be diagrammatically represented as a bubble linked to the target network working within the organization as illustrated in Figure 2.

VPNs' are used legitimately by business users to connect remotely and securely to the companies/ organisations network.

Figure 1. Connection to a network within an organization

Figure 2. Connection to a network within an organisation using a VPN

THE DARK SIDE OF ENGAGING WITH SOCIAL NETWORKING SITES (SNS)

The massive diffusion of SNS has led to some adverse and undesirable societal consequences (Salo, Mantymaki, & Islam, 2018). SNS both on the surface web and the deep web can have a dark negative side. This chapter focuses on the dark side of engaging with SNS on the surface web. Some of the negative effects include: addiction or addictive behaviour, child pornography, cyberbullying, fake news, Fear Of Missing Out (FOMO), social comparisons, stalking, amongst many others.

Addiction or Addictive Behaviour

“The powerful and addictive sharing functionality of social media presents risks to those who share content and those who consume the content that is shared” (Baccarella et al., 2018, p. 433). Once content is shared through the use of social media, there is no knowing how many people around the world will see, download, or save the content. Shared information, pictures and videos can go viral very quickly, once this content is made publically available there is no way that anyone can delete every instance or trace of the content. In a study conducted by Wang et al. (2018) the findings suggest that addiction to SNS could potentially be a risk factor for the onset of depression in teenagers. The suggestion that addiction to social networking sites could trigger depression in teenagers is a serious issue that deserves further research. Addiction to SNS could also be a risk factor for the onset of depression in adults.

Kanat-Maymon, Almog, Cohen, & Amichai-Hamburger (2018) suggest that the roles of self-esteem and contingent self-worth (CSW) may possibly be associated with excessive and inappropriate use of SNS. It is impossible to know the extent to which users are involved with or subjected to inappropriate use of SNS. In a study conducted by (Atroszko et al., 2018) the findings suggest that “When suggested tentative personality risk factors model were investigated, addictive Facebook use was related to being female, being older, extraverted, narcissistic, having low self-efficacy as well as feeling loneliness and social anxiety” (Atroszko et al., 2018, p. 335). Unfortunately, some users do not realise the negative effects that addictive use of SNS can have on their lives and the lives of others. The findings of Casale & Fioravanti (2018) suggest that there is “a positive association between grandiose narcissism and problematic SNS use” (p. 317). SNS are a recent phenomenon in the history of mankind, further research is needed to ascertain the influence of addictive use of SNS on personal relationships and general well-being.

Excessive use of modern technological devices for social networking can have negative consequences on the following: quality time spent engaging with friends and family (Osatuyi & Turel, 2018), work environment and performance (Moqbel & Kock, 2018; Osatuyi & Turel, 2018), exercising, involvement

with many other activities that are good for both physical and mental welfare, and a reduction in positive emotions (Moqbel & Kock, 2018). “Facebook addiction is related to higher stress, lower general health and lower sleep quality” (Atroszko et al., 2018, p. 335). These negative effects need to be taken seriously and appropriately addressed.

Internet addiction is a recent and changing phenomenon (Mubarak & Quinn, 2017), which has not previously affected society as other addictions have done, therefore, further research is required to promote official recognition of this problem and possibly identify suitable treatments to resolve this problem before social engagement is negatively affected by obsessive use of the internet and SNS. Mubarak & Quinn (2017) suggest that “it is likely that individuals experiencing internet addiction may engage in problem behaviours in cyberspace and create social and psychological problems to other internet users” (p. 9).

Child Pornography

Dalins, Wilson & Carman (2018) suggest that law enforcement agencies show more concern for sites hosting Child Exploitation Materials (CEM) than sites hosting child pornography in the form of cartoons. The sharing of content depicting the exploitation of children for the gratification of others poses a serious challenge to law enforcement agencies. Child pornography and exploitation occurs almost 25% more often than adult pornography (Dalins et al., 2018).

“One site advertised itself as a ‘support’ forum, though in terms of supporting and normalizing paedophilia rather than aiding persons avoid such behavior and actions” (Dalins et al., 2018, p. 71), whilst other sites offered education and training on grooming vulnerable children (Dalins et al., 2018). SNS within the deep and dark web require policing by government supported agencies to infiltrate such sites and monitor the activities of people engaging with these sites.

Cyberbullying

In a study conducted by Mc Hugh, Wisniewski, Rosson, & Carroll (2018) the findings were that “cyberbullying, sexual solicitations, and exposure to explicit content (but not information breaches) can cause symptoms of PTSD” (p. 1182). Post-Traumatic Stress Disorder (PTSD) is a mental health disorder that affects some people who have been exposed to or have personally experienced some horrifying event, or others who have witnessed such events. Experiencing PTSD as a result of engaging with SNS indicates that there is a dark side to SNS. The Health Service Executive (HSE) have provided on their website some helpful advice and who to contact regarding online bullying (HSE, 2018a). “Cyberbullying may be a way to intentionally harm individuals, while oversharing photos of positive experiences unintentionally causes anxiety among those who live lives less glamorous” (Baccarella et al., 2018, p. 432). Some users may not intentionally aim to harm other users by oversharing, not all users will be harmed by the positive posts of others, but some users may through social comparison feel that their lot in life is not as glamorous or successful as others.

Fake News
